## Procedures:

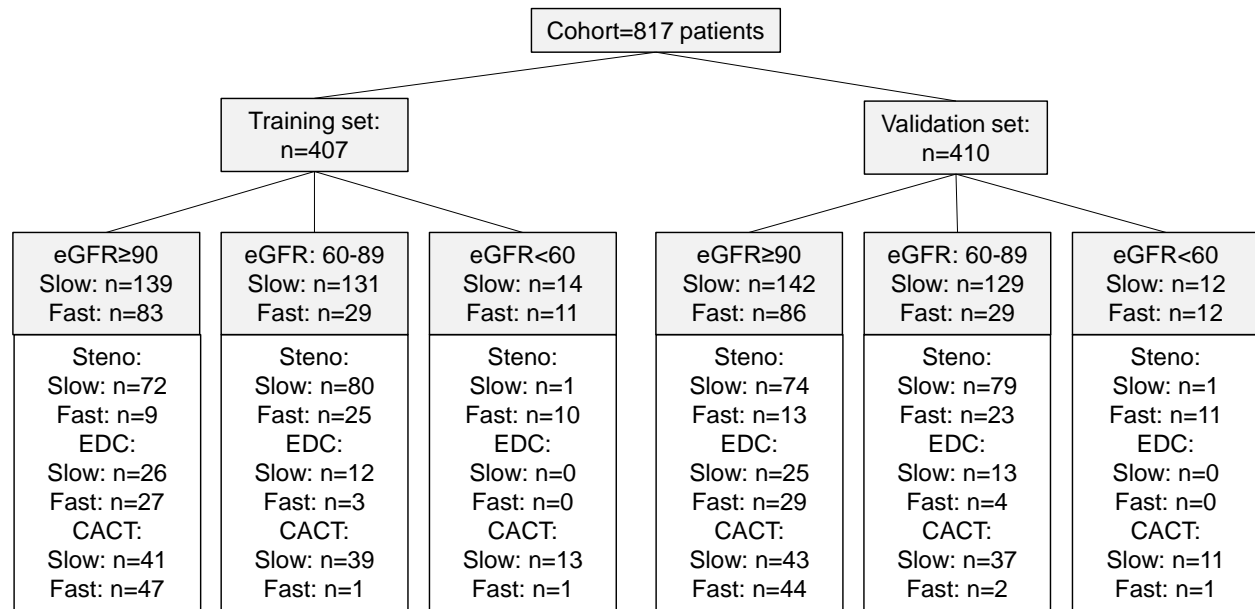

**Sample preparation and Mass Spectrometry:** We applied previously published procedures for lipid extraction(6; 7; 9), using the modified Bligh-Dyer method.(10) In brief, we retrieved 50  $\mu\text{L}$  of plasma and added water/methanol/dichloromethane at room temperature with 2:2:2 volume ratio, followed by spiking of internal standards: PC17:0/17:0, LPC 17:0, phosphatidylglycerol (PG) 17:0/17:0, PE 17:0/17:0, TAG 17:0/17:0/17:0, SM 18:1/17:0, and palmitate (C16-d9). After collection of the organic layer and drying under nitrogen, we reconstituted the samples in 100  $\mu\text{L}$  of Buffer B composed of acetonitrile/water/isopropyl alcohol (10:5:85) and 10 mM ammonium acetate ( $\text{NH}_4\text{OAc}$ ). The samples were further diluted to 5% sample/ 95% Buffer B, and 5  $\mu\text{L}$  was injected using a TurbolonSpray Ion Source into an AB Sciex Triple Quadrupole/QTRAP 6500+ mass spectrometer using a 1.8  $\mu\text{m}$ -particle, 50 mm  $\times$  2.1 mm Waters Acquity HSS T3 column (Waters Inc, Milford, MA) with the corresponding guard column in reverse phase. Buffer A for liquid chromatography was acetonitrile:water (40:60). The source voltage was 5500 V, temperature was 550° C, and current gas flow was 35, 50, and 60 psi. Declustering potential was 60 V, and entrance potential was 10 V with collision energy at 15 V. We scanned in both positive and negative modes in MS1 and MS2 in multiple reaction monitoring (MRM) mode for 20 minutes. Abundant TAG isotopomers were combined into one lipid feature.

For quantification of ACs(11), we added 500  $\mu\text{L}$  of methanol/chloroform/water (8:1:1) and 1  $\mu\text{L}$  of AC mixed internal standards to 25  $\mu\text{L}$  of thawed plasma for lipid extraction. Then, the supernatant was dried under nitrogen, resuspended by 50  $\mu\text{L}$  of water/acetonitrile (95:5) mixed with 15 mM  $\text{NH}_4\text{OAc}$ . Five  $\mu\text{L}$  was injected into the Agilent 6410 Triple quadrupole tandem mass spectrometer (Agilent, Santa Clara, CA) for data acquisition in MRM mode as reported previously. Each lipid molecule was quantified using the authenticated internal standards with known concentrations and a calibration curve corresponding to each internal

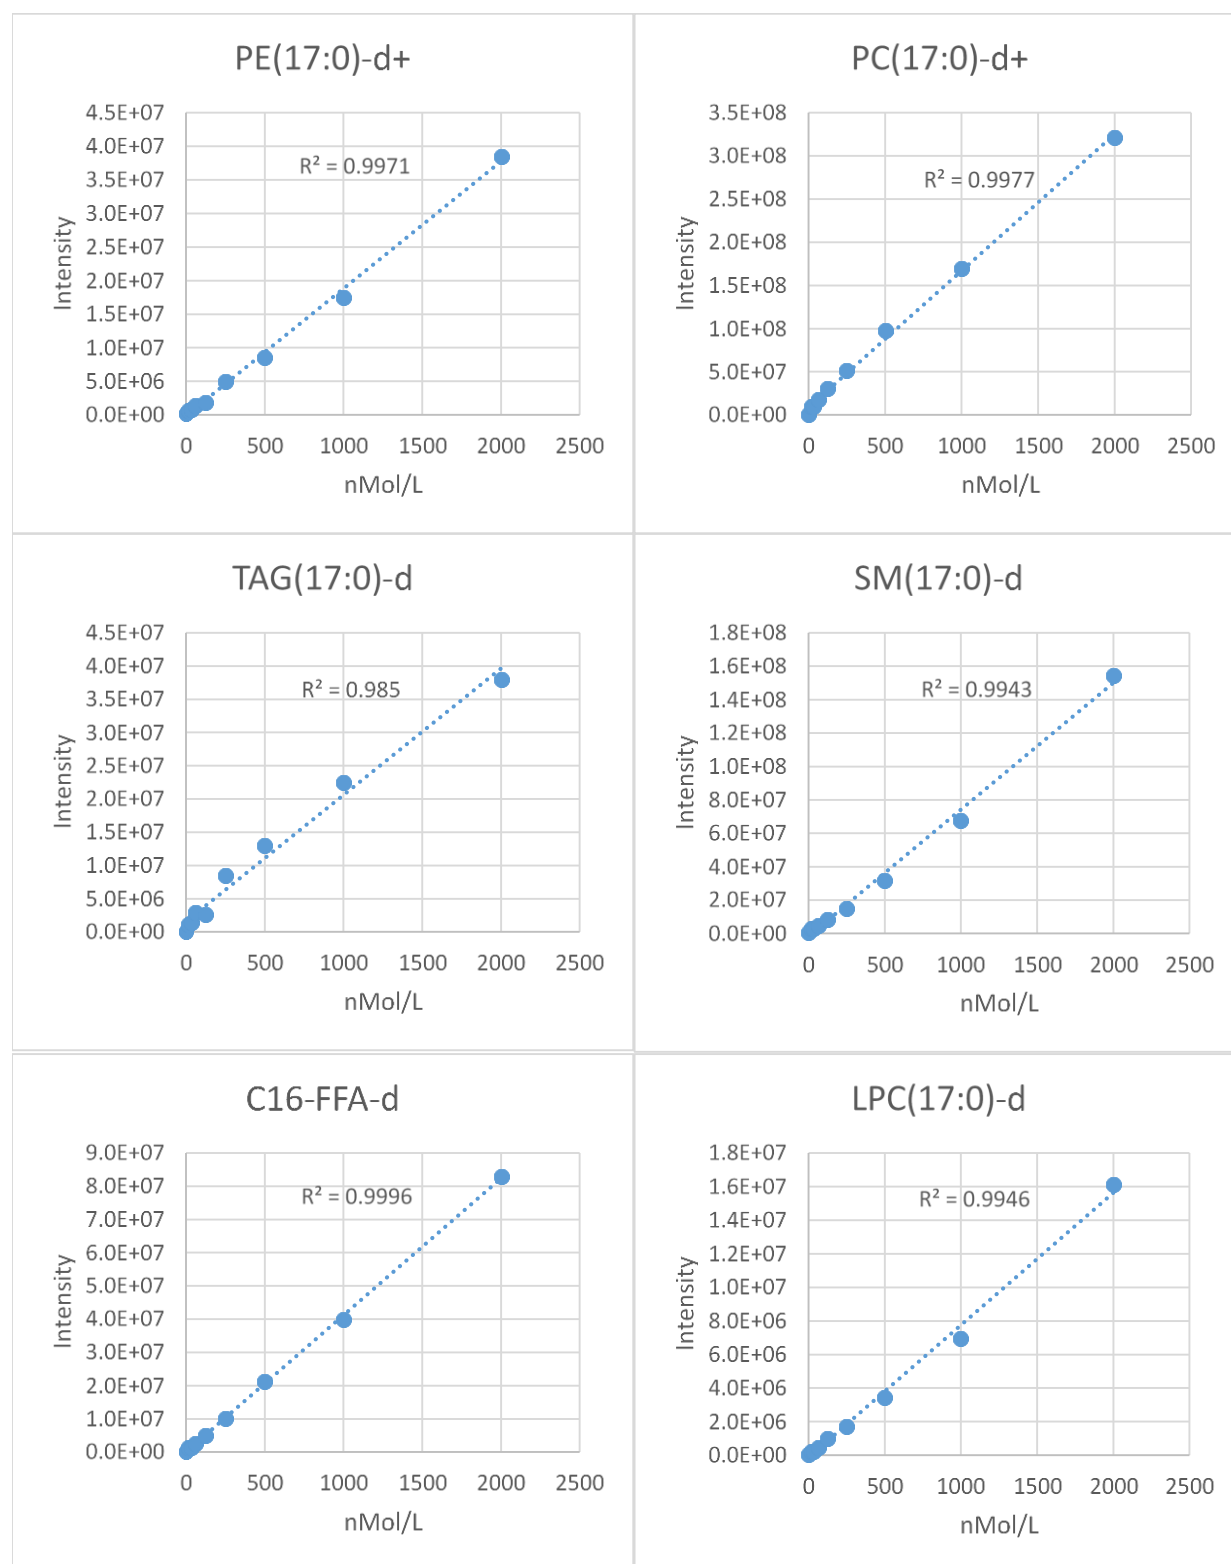

standard (sFig 2). Lipids of the DAG and CE classes were normalized and quantified using the TAG internal standard. The overall lower limit of detection was <15 nm/L, which is significantly below the natural abundance of measured lipids in plasma. Lipids are stable metabolites which do not undergo degradation upon proper storage at -80°C.

**Quality control:** Investigators conducting the lipidomic study were blinded to the clinical data until after generating the lipidomic data and sharing the data with other team members. We randomized the samples into 6 different batches for mass spectrometry runs. A reference sample (pooled plasma) was run up to 7 times at the beginning of each batch to assess the reproducibility of the mass spectrometry. A pool of test samples was run at the beginning and then after every 7 to 10 samples in the lipidomic study, and after every 12 to 15 samples in AC study to assess stability of the runs over time, inter- and intra-assay coefficient of variation, and the batch-to-batch variability (sFig 3 and 4).

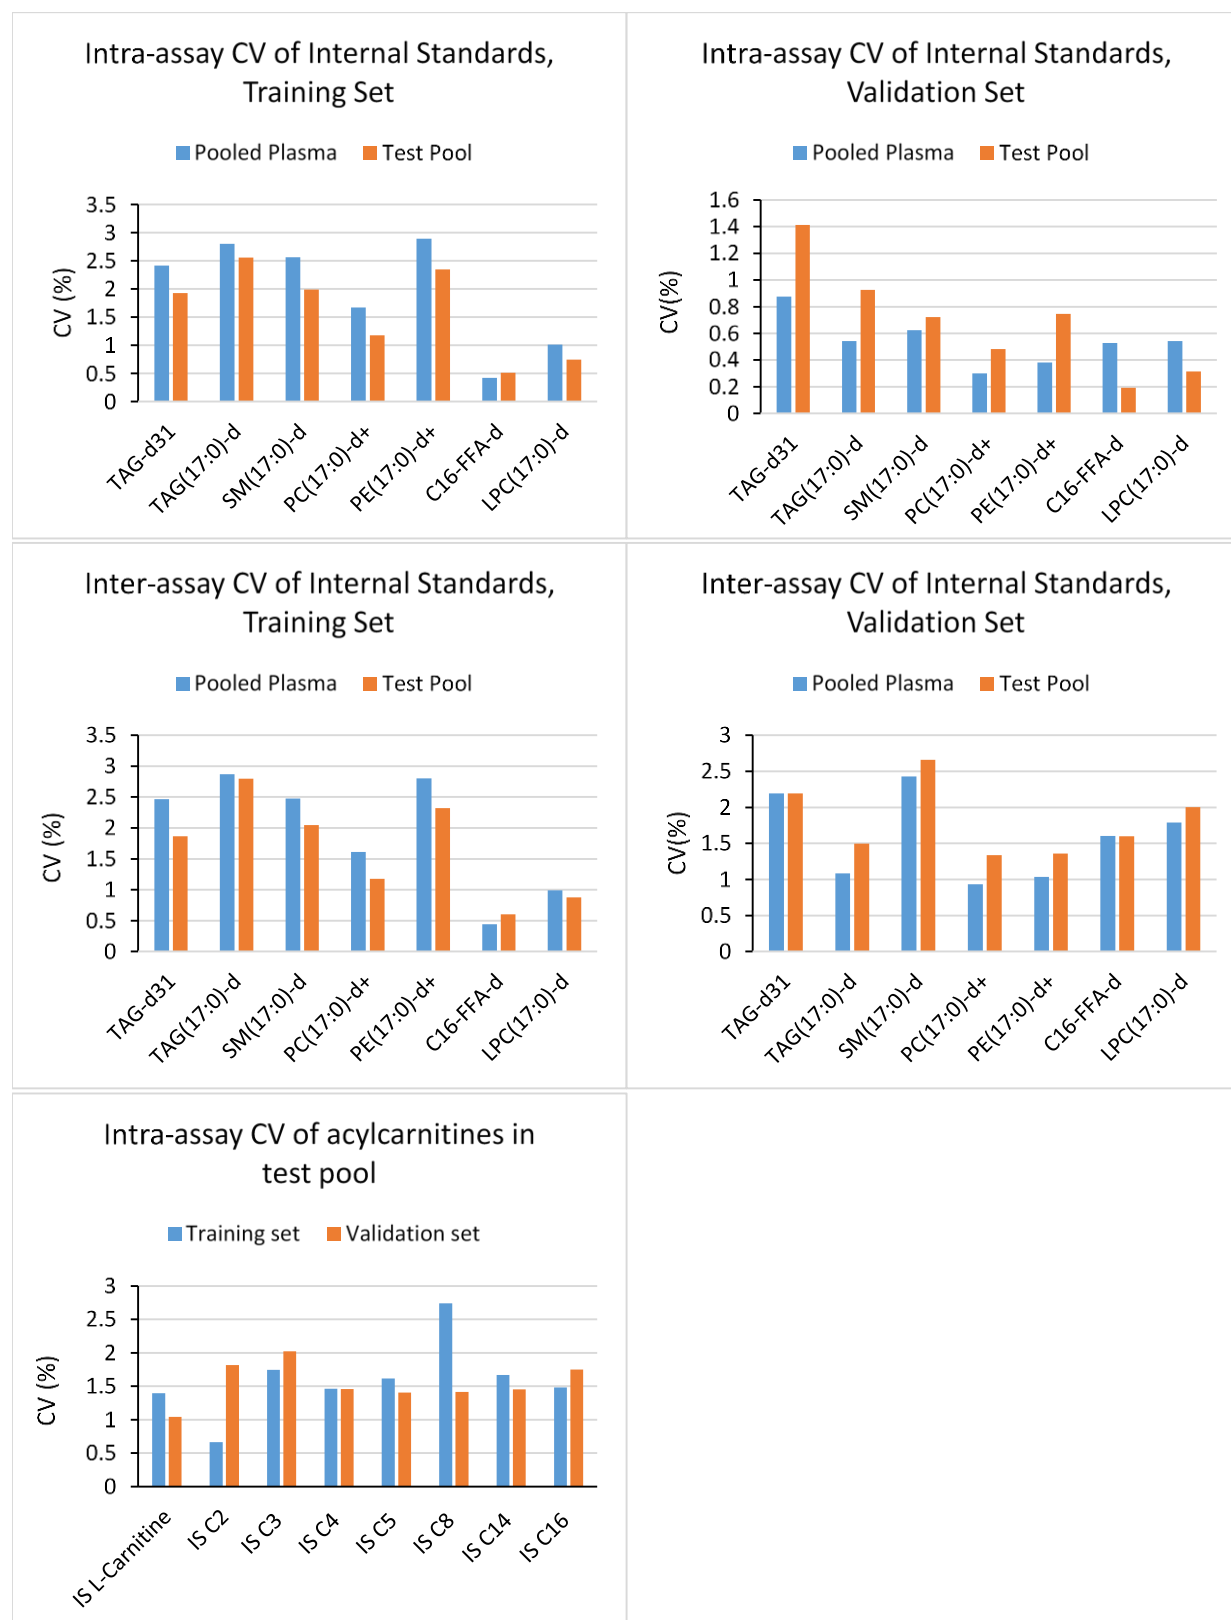

**sFig 1:** The study cohort structure showing the distribution of participants with slow versus fast decliners of eGFR (mL/min/1.73 m<sup>2</sup>) in the Training and Validation sets stratified by categories of eGFR at baseline. eGFR: estimated glomerular filtration rate; EDC, Epidemiology of Diabetes Complications study; CACT, Coronary Artery Calcification in Type 1 Diabetes study.

**sFig 2.** Calibration curves of authenticated internal standards in plasma, with lower limit of quantification < 30 nmol/L and lower limit of detection < 15 nmol/L.

**sFig 3.** Comparing coefficients of variation (CV) of internal standards in test pools and pooled plasma in the Training and Validation sets.

**sFig 4.** Illustration of minimal batch-to-batch variation.

**A)** Distribution of lipidomic platform internal standards in test pools and pooled plasma during sequential runs with the Training set

**B)** Distribution of lipidomic platform internal standards in test pools and pooled plasma in sequential runs with the Validation set

**C)** Distribution of endogenous acylcarnitines on a log2 scale in pooled plasma in sequential runs with the Training and Validation sets

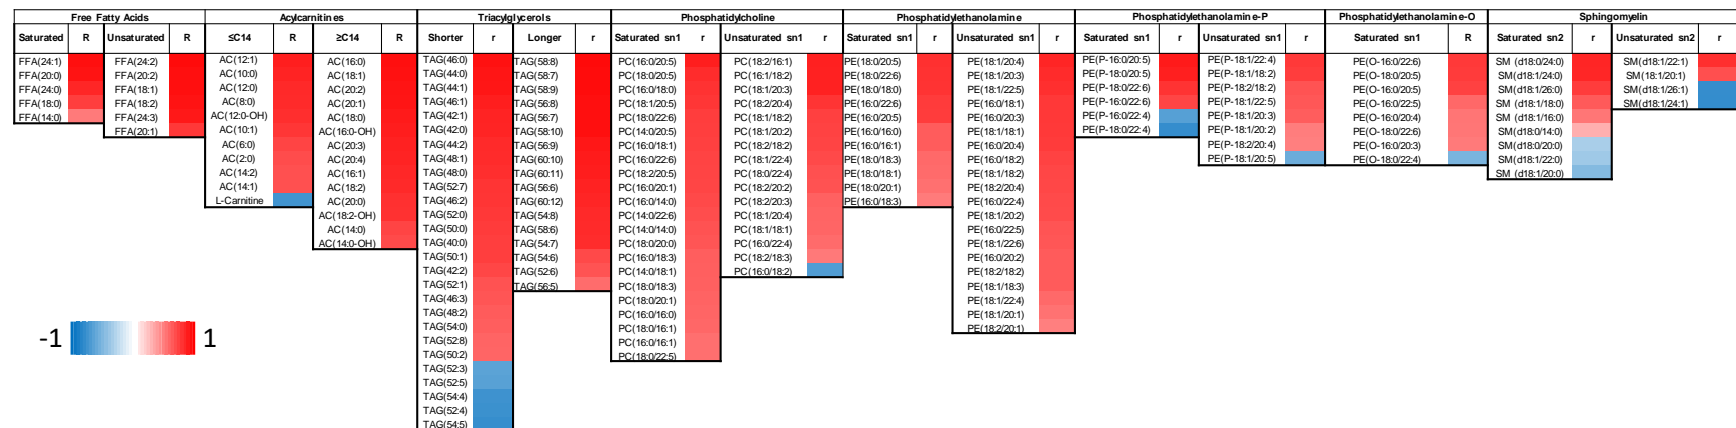

**sFig 5.** The top 47 lipids with differential levels in rapid versus slow eGFR decliners in the training set and validation set. Mean change is the standardized mean difference. Logistic regressions are unadjusted and adjusted univariate for each model. Adjustment was for age, sex, race, duration of diabetes, hypertension, use of angiotensin-converting-enzyme inhibitor or angiotensin receptor blocker, use of lipid lowering agents, and baseline mean arterial pressure, HbA1c, eGFR and urine albumin-creatinine ratio. AC, acylcarnitine; CE, cholesteryl-ester; CI, confidence interval; FDR, false discovery rate; FFA, free fatty acid; LR, logistic regression; OR, odds ratio; PC, phosphatidylcholine; PE, phosphatidylethanolamine; TAG, triacylglycerol.

**sFig 6.** Constituents and their Pearson correlation coefficients with the corresponding principal component. AC, acylcarnitine; FFA: free fatty acid; PC: phosphatidylcholine; PE; phosphatidylethanolamine; PE-P, PE with alkenyl ether substitute at sn-1 carbon; PE-O, PE with alkyl ether substitute at sn-1 carbon of the glycerol backbone; SM: sphingomyelin; TAG: triacylglycerol.

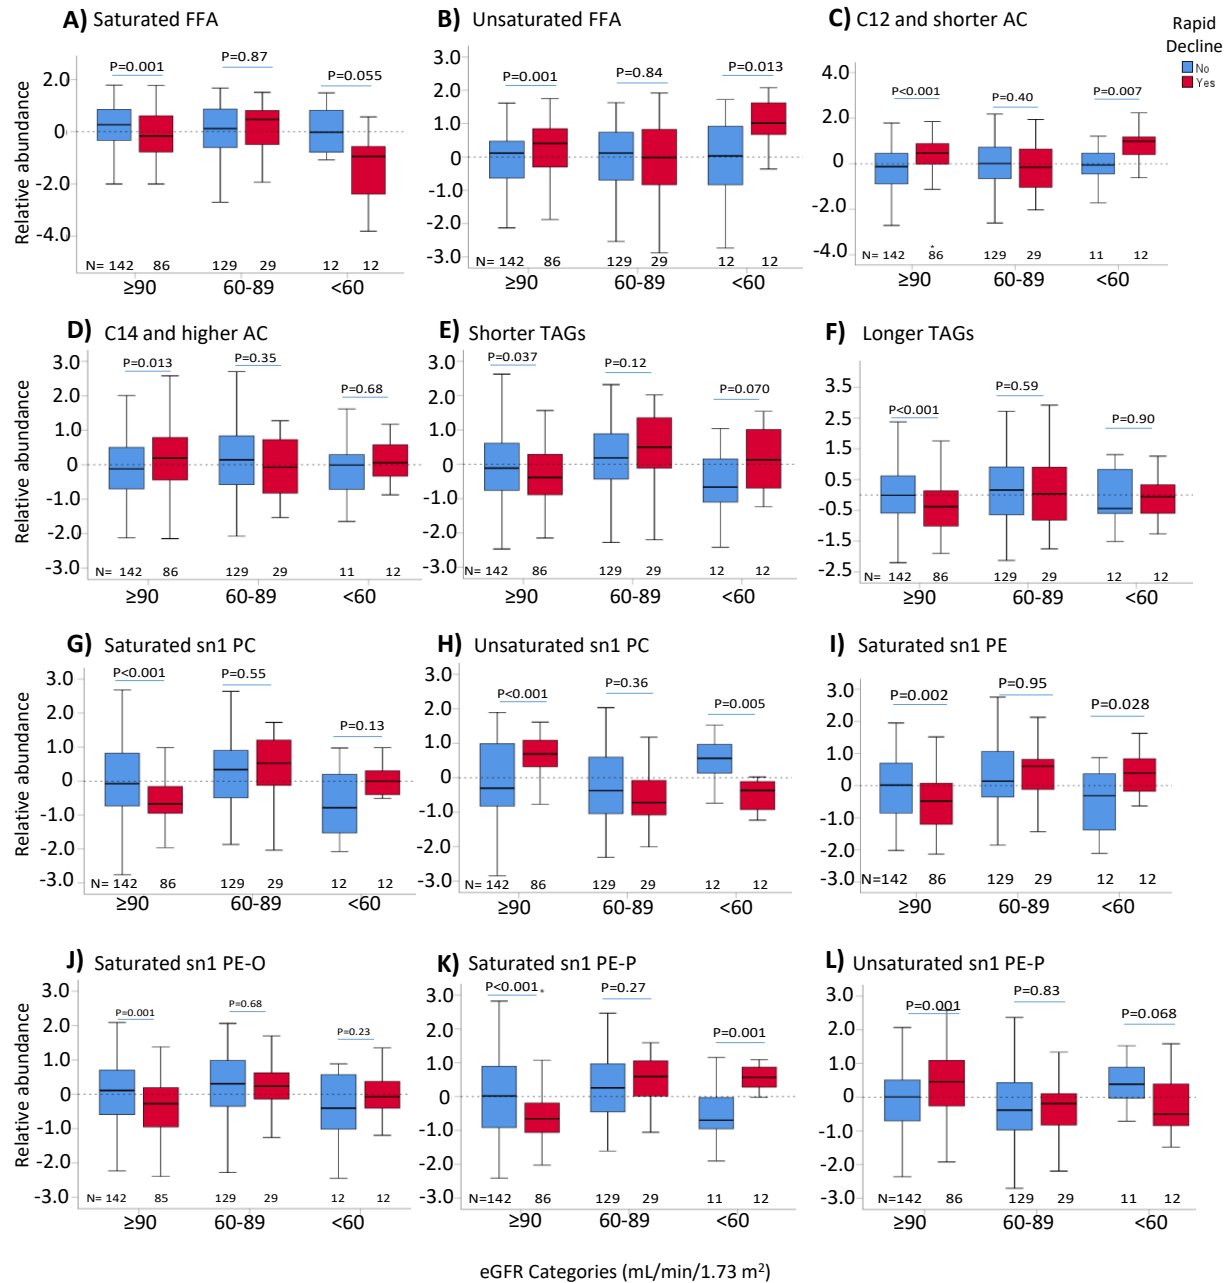

### A) Training set

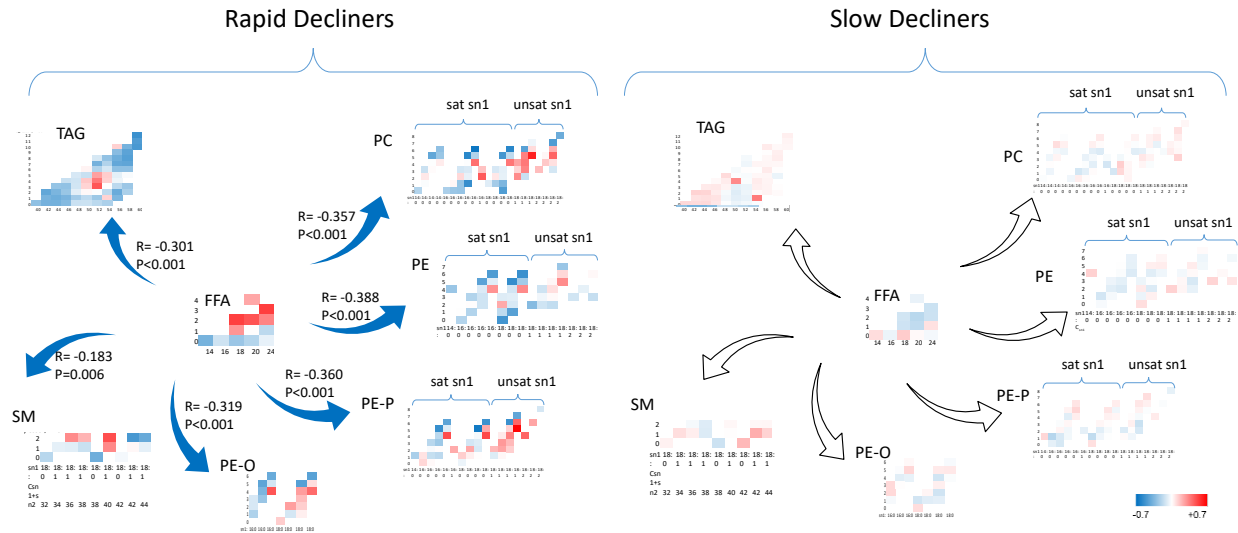

### B) Validation set

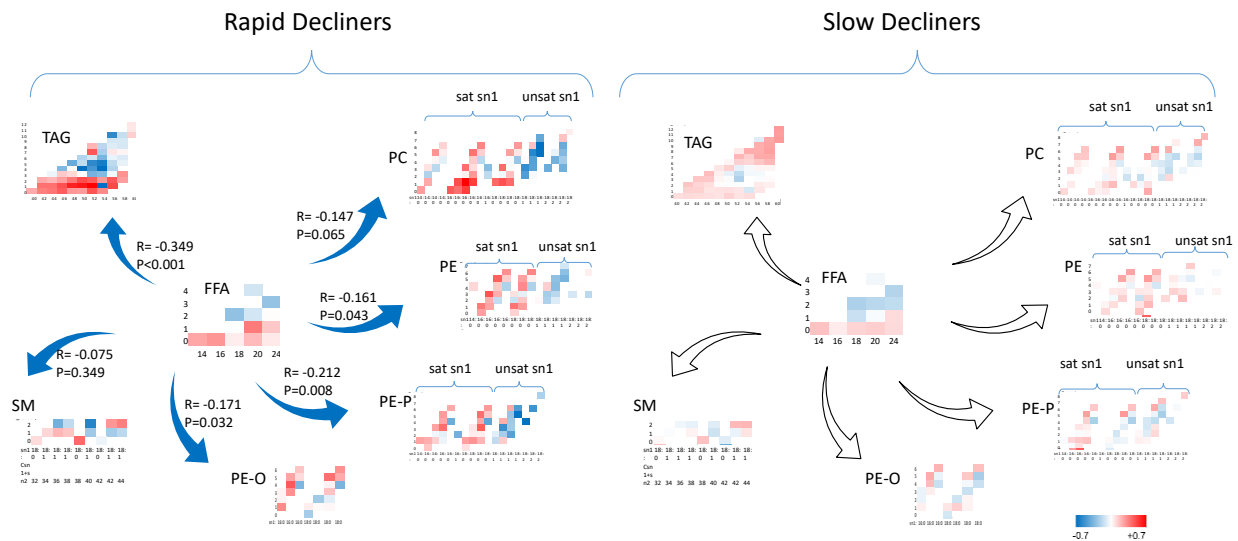

**sFig 7.** Comparing principal components representative of free fatty acid (FFA), acylcarnitines (AC), triacylglycerols (TAG), phosphatidylcholines (PC), and phosphatidylethanolamines (PE) in rapid versus slow decliners of eGFR stratified by eGFR categories in the validation set. Trend p values of lipids by eGFR categories were 0.002 for shorter TAGs, 0.034 for longer TAGs, and <0.001 for other phospholipids in rapid decliners.

### A) eGFR $\geq 90$ mL/min/1.73m<sup>2</sup>

### B) eGFR 60-89 mL/min/1.73m<sup>2</sup>

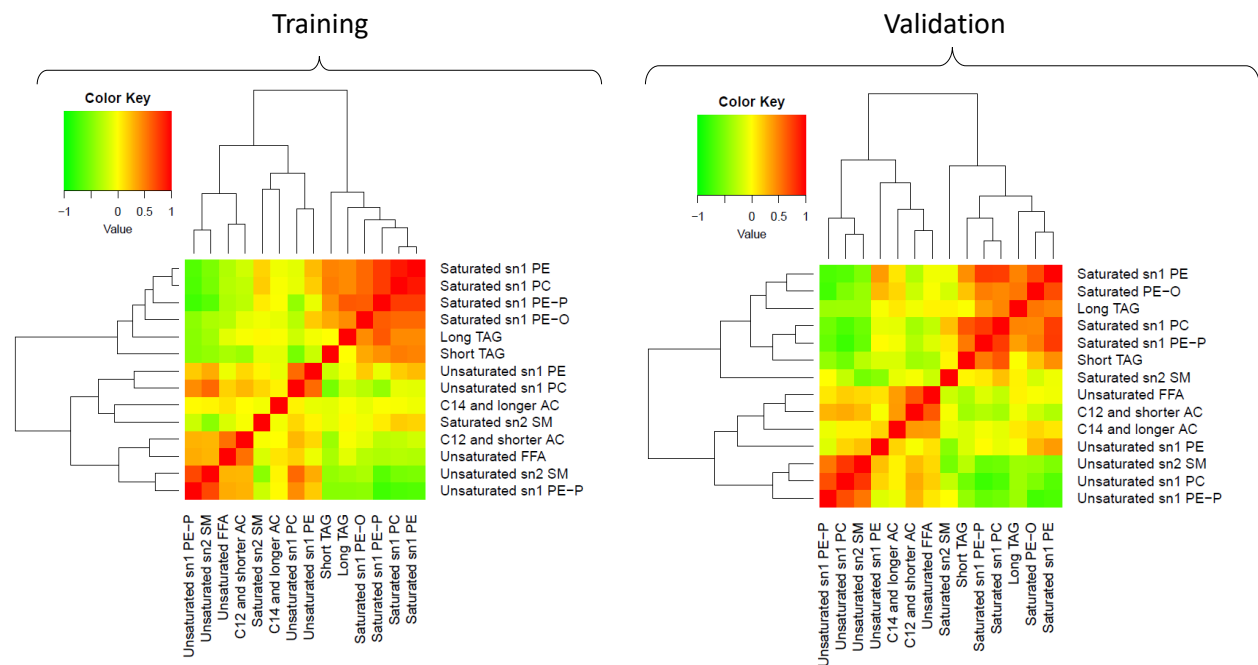

**sFig 8.** Differential abundance of various lipids during rapid versus slow eGFR decline by eGFR categories. **A:** In rapid decliners with baseline eGFR  $> 90$  mL/min/1.73m<sup>2</sup> higher abundance of unsaturated FFAs, and unsaturated phospholipids at sn1 carbon, low abundance of saturated phospholipids at sn1 carbon and inverse correlations between unsaturated FFAs and saturated phospholipids at sn1 suggest shift of unsaturated FFAs in construct of unsaturated phospholipids. **B:** In rapid decliners with baseline eGFR of 60-89 mL/min/1.73m<sup>2</sup>, relatively higher abundance of saturated FFAs, saturated phospholipids at sn1 carbon, lower unsaturated

phospholipids at sn1 carbon, and inverse correlations between unsaturated FFAs and saturated PCs at sn1 suggest dominant shift of saturated FFAs in construct of saturated PCs at sn1 carbon. The X axis of each plot is carbon number and the Y axis is number of double bonds for the corresponding lipid class. Values are z-score mean standardized values for each lipid and R is the partial correlation between unsaturated FFA and unsaturated complex lipids adjusted for eGFR and albumin-creatinine ratio. AC, acylcarnitine; FFA, free fatty acid; PC, phosphatidylcholine; PE, phosphatidylethanolamine; SM, sphingomyelin; sat sn1, saturated acyl chain at sn1 carbon; TAG, triacylglycerol; unsat sn1, unsaturated acyl chain at sn1 carbon.

**sFig 9.** System level lipids. **A.** Inter-class lipid factor correlations in the training and validation subsets reveal high direct correlation between saturated lipids and inverse correlation between saturated and unsaturated lipids. **B.** Classification power of lipid factors alone and when added to clinical variables (age, sex, diabetes duration, HbA1c, mean arterial pressure, eGFR, and Log<sub>2</sub> albumin-creatinine ratio) in the training set and replication in the validation set. AC, acylcarnitine; CI, confidence interval; uFFA, unsaturated free fatty acids; PC, phosphatidylcholine; PE, phosphatidylethanolamine; sPE-P, saturated PE with alkenyl ether substitute at sn-1 carbon; PE-O, PE with alkyl ether substitute at sn-1 carbon of the glycerol backbone; SM, sphingomyelin; TAG, triacylglycerol.

**sFig 10: A)** Alteration of fatty acids and complex lipids in rapid decliners of eGFR compared to slow decliners by eGFR categories. **B)** Comparing alterations of fatty acids and complex lipids in early stage (GFR $\geq$ 90 mL/min/1.73m<sup>2</sup>) in rapid decliners in type 1 and type 2 diabetes. **C)** Proposed mechanisms of rapid eGFR decline involves diminished sensitivity of adipose tissue to insulin at early stage in insulin deficiency leading to diminished lipolysis and decreased circulating levels of TAGs, and relatively higher incorporation of unsaturated FFAs in construct of unsaturated phospholipids at the acyl chain in sn1 carbon of the glycerol backbone. With stage progression of CKD and CKD mediated higher insulin resistance, relative circulating levels of TAGs increase. In parallel, higher abundance of saturated FFAs due to insulin resistance and upregulation of de novo lipogenesis contributes to its higher incorporation in construct of saturated phospholipids at the acyl chain in sn1 carbon position of the glycerol backbone.

**A)** Comparing lipid alterations in rapid decliners by eGFR categories

| Lipids           | GFR>90 mL/min | GFR 60-90 mL/min | GFR <60 mL/min |
|------------------|---------------|------------------|----------------|
| Saturated FFAs   | ↓             | ↔ or ↑           | ↔ or ↑         |
| Unsaturated FFAs | ↑             | ↔ or ↓           | ↔ or ↓         |
| Long Chain AC    | ↔ or ↑        | ↔ or ↑           | ↔ or ↑         |
| Shorter TAGs     | ↓             | ↑                | ↑              |
| Longer TAGs      | ↓             | ↑                | ↑              |
| Saturated PCs    | ↓             | ↑                | ↑              |
| Unsaturated PCs  | ↑             | ↓                | ↓              |
| Saturated PEs    | ↓             | ↑                | ↑              |
| Saturated PE-O   | ↓             | ↑                | ↑              |
| Saturated PE-P   | ↓             | ↑                | ↑              |
| Unsaturated PE-P | ↑             | ↓                | ↓              |

**B)** Comparing lipid alterations in fast progressors with baseline GFR $\geq$ 90 mL/min by type of diabetes

| Lipids             | Type 1 DM | Type 2 DM |
|--------------------|-----------|-----------|
| Saturated FFA      | ↓         | ↑         |
| Unsaturated FFA    | ↑         | ↓         |
| Long Chain AC      | ↔ or ↑    | ↓         |
| Shorter Chain TAGs | ↔ or ↓    | ↓         |
| Longer Chain TAGs  | ↓         | ↑         |
| Unsaturated PEs    | ↑         | ↑         |

**C)** Proposed lipidomic mechanisms of DKD progression in type 1 diabetes

**eGFR  $\geq$ 90 mL/min:**

**eGFR 60-90 mL/min:**
