## **SUPPLEMENTAL MATERIALS**

Study Population

Fecal sample collection and 16S rRNA gene sequencing

## **SUPPLEMENTAL FIGURES**

Figure S1. Flow chart of participants included in the present study

Figure S2. Relative risks of type 2 diabetes according to interquartile range of  $\gamma$ -linolenic acid and BMI

## **SUPPLEMENTAL TABLES**

Table S1. Baseline population characteristics by quartiles of erythrocyte linoleic acid and arachidonic acid (N=2,731)

Table S2. Baseline characteristics for participants with and without follow-up information (N=3,265)

Table S3. Baseline characteristics for participants with and without 16S profiling (N=2,731)

Table S4. Correlation of dietary n-6 fatty acids and erythrocyte n-6 fatty acids

Table S5. Dietary sources of n-6 polyunsaturated fatty acids

Table S6. The association between erythrocyte n-6 fatty acids and type 2 diabetes after imputing missing values of type 2 diabetes (N=3,265)

Table S7. The association between erythrocyte n-6 fatty acids and type 2 diabetes excluding cases ascertained only by fasting glucose (N=2,679)

Table S8. Numbers of type 2 diabetes cases diagnosed with fasting glucose, HbA1c, or self-reported diabetes medication

Table S9. Association of erythrocyte n-6 fatty acid biomarkers with incident type 2 diabetes adjusting for additional potential covariates

Table S10. Association of erythrocyte n-6 fatty acid biomarkers with microbiota  $\alpha$ -diversity (N=1,591)

Table S11. Association between erythrocyte n-6 fatty acid biomarkers and microbiota  $\alpha$ -diversity adjusting for additional dietary fiber intake (N=1,581)

Table S12. Association of erythrocyte n-6 fatty acid biomarkers with incident type 2 diabetes among participants with 16S profiling (N=1,591)

Table S13. Summary statistics of the mediation analysis for  $\alpha$ -diversity indicators

Table S14. Association of erythrocyte n-6 fatty acid biomarkers with microbiota  $\beta$ -diversity (N=1,591)

Table S15. Results from Pairwise PERMANOVA analysis of  $\gamma$ -linolenic acid ( $\gamma$ C18:3n6) verses microbiota  $\beta$  diversity (N=1,591)

Table S16. Cross-sectional association of microbiota  $\alpha$ -diversity with type 2 diabetes (N=1,563)

Table S17. Cross-sectional association of microbiota  $\beta$ -diversity with type 2 diabetes (N=1,563)

Table S18. Association of taxonomic biomarkers of  $\gamma$ -linolenic acid ( $\gamma$ C18:3n6) with T2D-related traits

Table S19. The association between dietary n-6 fatty acids intake and type 2 diabetes (N=2,731)

Table S20. Association of dietary n-6 fatty acid intake with microbiota  $\alpha$ -diversity (N=1,591)

Table S21. Association of dietary n-6 fatty acid intake with microbiota  $\beta$ -diversity (N=1,591)

## **SUPPLEMENTAL MATERIALS**

### **Study Population**

Guangzhou Nutrition and Health Study (GNHS), is a community-based prospective cohort study conducted in urban areas of southern China. There were two waves of participant recruitment

using the same criteria as described previously(1): between 2008 and 2010 (n=3169), and between 2012 and 2013 (n=879).

At baseline, socio-demographic characteristics, lifestyles and dietary factors, and medical history of the participants were collected by face-to-face interviews using a structured questionnaire. Habitual dietary intakes over the past 12 months were collected by a validated food frequency questionnaire (FFQ) which included 79 items (2). Dietary macronutrients and fatty acids were adjusted for total energy intake using the residual method(3). Physical activity was assessed as total metabolic equivalent for task (MET) hours per day using a physical activity questionnaire including 19 items (4). Anthropometric parameters including height, weight, waist circumference and hip circumference were measured by trained nurses at the site after questionnaire interview. Body mass index (BMI) was calculated as weight (kg)/height (m)<sup>2</sup>, and waist-to-hip ratio (WHR) was calculated as waist circumference (cm)/hip circumference (cm).

Fasting blood samples at each visit were used to measure the standard clinical chemistry of participants. Erythrocytes were aliquoted within 2 hours of blood sampling and stored at -80°C. Fatty acid moieties of erythrocyte membranes were trans-methylated and measured as proportions (%) of total fatty acids by using gas chromatography (7890 GC, DB-23 capillary column 60m×0.25mm internal diameter×0.15µm film, Agilent, California, USA). Commercially available standards (Nu-Chek Prep, Minnesota, USA) were used to identify individual fatty acids (n=37) and quantify a relative peak strength of each. The intra-assay coefficients of variation for LA, GLA and AA were 6.4%, 12.8%, and 8.04%, respectively. Glycated hemoglobin (HbA1c) was measured by high performance liquid chromatography using Bole D-10 Hemoglobin A1c Program on Bole D-10 Hemoglobin Testing System. Fasting glucose, high-density lipoprotein cholesterol (HDL), low-density lipoprotein cholesterol (LDL), total cholesterol (TC) and triglycerides (TG) were measured by colorimetric methods using a Roche cobas 8000 c702 automated analyzer (Roche Diagnostics, Shanghai, China). Fasting insulin was determined by electrochemiluminescence immunoassay using a Roche Cobas 8000/e602 immunoanalyzer (Roche Diagnostics, Shanghai, China). Insulin resistance was evaluated by the homeostasis model assessment of insulin resistance (HOMA-IR) calculated as fasting insulin (µIU/mL) × fasting glucose (mmol/ mL)/22.5. β-cell function was evaluated by the homeostasis model assessment model (HOMA-β) calculated as  $20 \times \text{fasting insulin } (\mu\text{IU/mL}) / (\text{fasting glucose (mmol/ mL)} - 3.5)$ . Non-HDL was calculated as TC (mmol/L) – HDL-C(mmol/L). The intra-assay coefficients of variation were 0.75% for HbA1c, 2.5% for glucose, 4.3% for HDL, 3.1% for LDL, 3.1% for TC, 5.8% for TG, and 5.8% for insulin respectively.

### **Fecal sample collection and 16S rRNA gene sequencing**

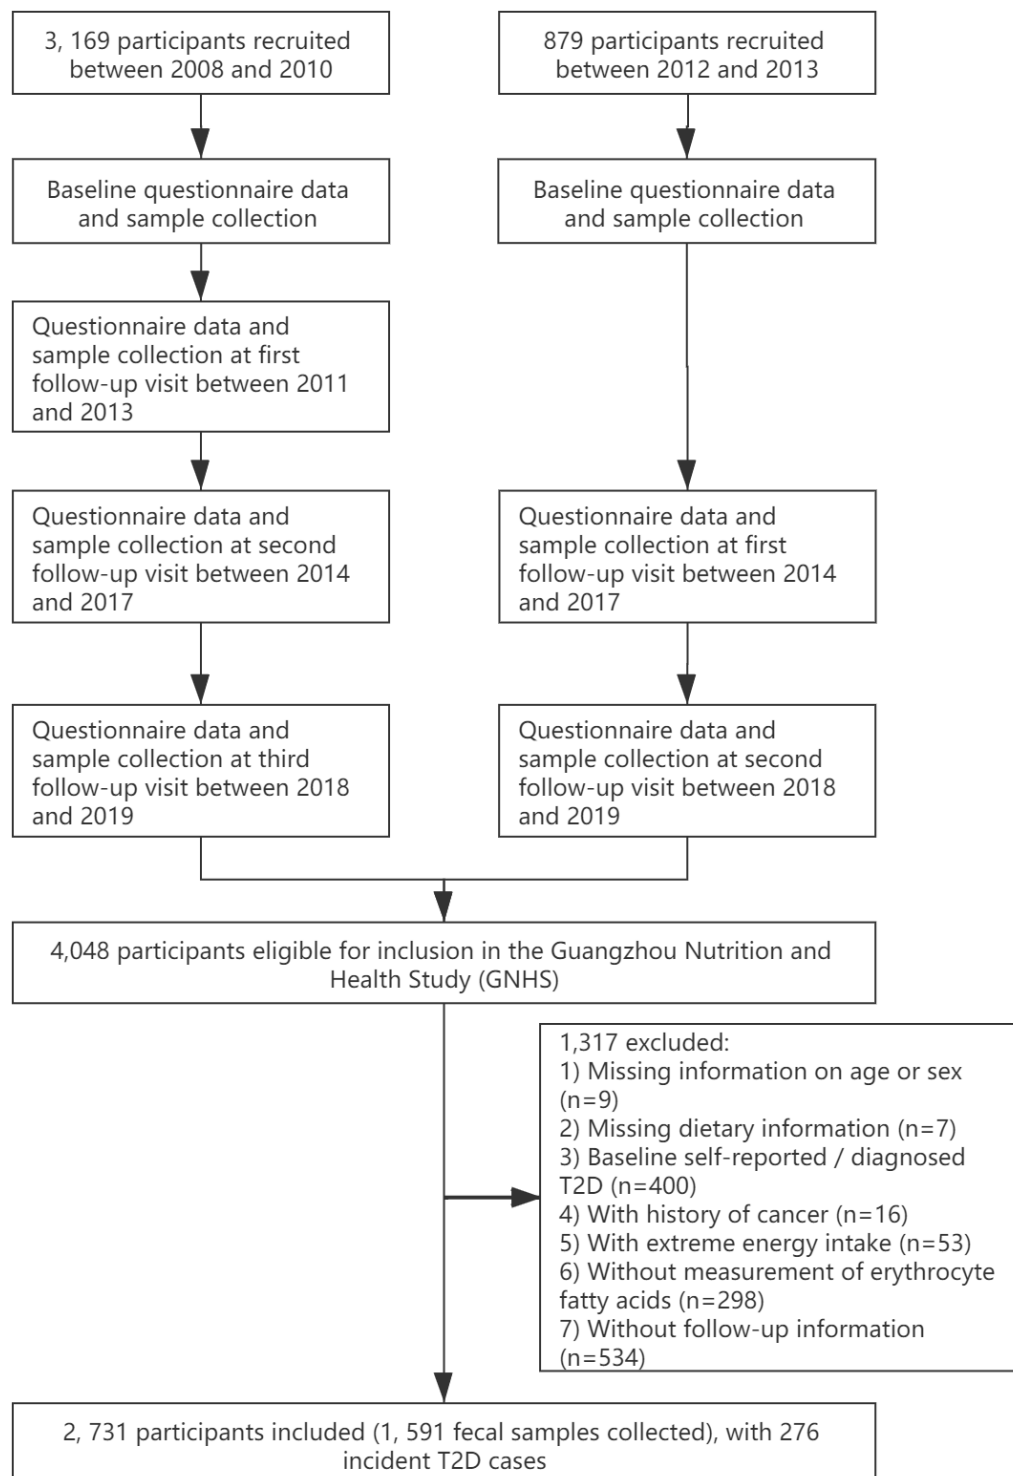

Fecal samples were collected on the examination day during follow-up visits and then were kept at 4 °C within four hours of donation before keeping at -80 °C. Microbial DNA was extracted from each sample using the QIAamp DNA Stool Mini Kit (Qiagen, Hilden, Germany) following the manufacturer's instruction. DNA concentrations were determined using the Qubit quantification system (Thermo Scientific, Delaware, US). All extracted DNA was stored at -20 °C for further sequencing.

The V3-V4 hypervariable region of the 16S rRNA gene was amplified from genomic DNA using primers 341F (5'-CCTACGGGNGGCWGCAG-3') and 805R (5'-GACTACHVGGGTATCTAATCC-3'). PCR reaction was performed in microtiter plates with a 50  $\mu$ L mixture consisting of 1X KAPA HiFi Hot start Ready Mix, 0.1  $\mu$ M primer 341 F, 0.1  $\mu$ M primer 805 R, and 12.5 ng template DNA. Reactions were run in a T100 PCR thermocycle (BIO-RAD) according to the following cycling program: 3 min of denaturation at 94 °C, followed by 18 cycles of 30 s at 94 °C (denaturing), 30 s at 55 °C (annealing), and 30 s at 72 °C (elongation), with a final extension at 72 °C for 5 min. Subsequently, the amplified products were checked by 2% agarose gel electrophoresis and ethidium bromide staining. Amplicons were quantified using the Qubit quantification system (Thermo Scientific, Wilmington, DE, US) following the manufacturers' instructions. Sequencing primers and adaptors were added to the amplicon products in the second PCR step as follows 2  $\mu$ L of the diluted amplicons were mixed with a reaction solution consisting of 1 $\times$ KAPA HiFi Hotstart ReadyMix, 0.5  $\mu$ M fusion forward and 0.5  $\mu$ M fusion reverse primer, 30 ng Meta-gDNA (total volume 50  $\mu$ L). The PCR was run according to the cycling program above except with cycling number of 12. The amplification products were purified with Agencourt AMPure XP Beads (Beckman Coulter Genomics, MA, USA) according to the manufacturer's instructions and quantified as described above. Equimolar amounts of the amplification products were pooled together in a single tube. The concentration of the pooled libraries was determined by the Qubit quantification system.

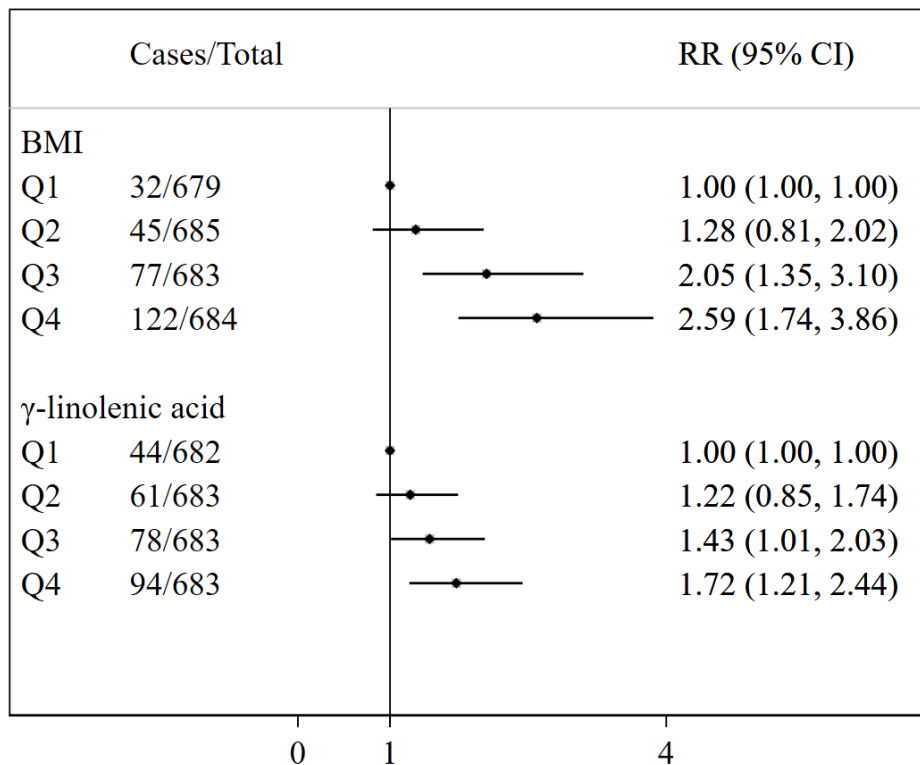

Amplicon sequencing was performed on the Illumina MiSeq System (Illumina, San Diego, USA). Fastq-files were demultiplexed, merge-paired, quality filtered by Quantitative Insights into Microbial Ecology (QIIME) software (version 1.9.0) (5). To obtain effective reads, marker gene Illumina sequence data, chimeric sequences ('consensus') and low-quality regions of the sequences were detected and filtered. Filtered sequences were clustered into operational taxonomic units (OTUs) with 97% similarity. Taxonomy of the OTUs was assigned using the Greengenes Database (version 13\_8)(6). To calculate  $\alpha$ -diversity, four indicators were applied: Observed OTUs and Chao index (representing community richness), Shannon's diversity index and Simpson index (representing community diversity).

## SUPPLEMENTARY FIGURES

**Figure S1. Flow chart of participants included in the present study**

**Figure S2. Relative risks of type 2 diabetes according to the interquartile range of  $\gamma$ -linolenic acid and BMI\***

\*Multivariable-adjusted RRs (95% CIs) were calculated for Q2-Q4 of the erythrocyte n-6 fatty acids and BMI using Q1 as the reference group. Covariates included age, sex, BMI, waist-hip ratio, education, household income, smoking and alcohol drinking status, physical activity, total energy intake, family history of diabetes, baseline erythrocyte total n-3 PUFAs and fasting glucose. Abbreviations: BMI, body mass index; CI, confidence interval; PUFAs, polyunsaturated fatty acids; RR, risk ratio.

## SUPPLEMENTAL TABLES

**Table S1. Baseline population characteristics by quartiles of erythrocyte linoleic acid and arachidonic acid (N=2,731) \***

	Linoleic acid (C18:2n6)				Arachidonic acid (C20:4n6)			
	Q1 (N=682)	Q2 (N=683)	Q3 (N=683)	Q4 (N=683)	Q1 (N=682)	Q2 (N=683)	Q3 (N=683)	Q4 (N=683)

	Multiple imputation <sup>‡</sup>	1.00 (Ref)	1.06 (0.78, 1.44)	1.04 (0.74, 1.46)	1.07 (0.78, 1.46)	0.74

\*Multivariable-adjusted RRs (95% CIs) were calculated for Q2-Q4 of the erythrocyte n-6 fatty acids using Q1 as the reference group. Covariates included age, sex, BMI, waist-hip ratio, education, household income, smoking and alcohol drinking status, physical activity, total energy intake, family history of diabetes, baseline erythrocyte total n-3 PUFAs and fasting glucose. *p* value for trend was calculated based on per quartile increase in the corresponding PUFA. Abbreviations: BMI, body mass index; CIs, confidence intervals; PUFAs, polyunsaturated fatty acids; Q, quartile; RRs, risk ratios.

<sup>†</sup>Simple imputation: assuming the participants with missing outcome data did not develop T2D.

<sup>‡</sup>Multiple imputation: data were imputed using multivariate imputation with a logistic imputation model for the outcome for 10 rounds.

**Table S7. The association between erythrocyte n-6 fatty acids and type 2 diabetes excluding cases ascertained only by fasting glucose (N=2,679) \***

Erythrocyte n-6 fatty acids	Multivariable-adjusted RRs (95% CIs)				
	Q1	Q2	Q3	Q4	<i>p</i> for trend
Linoleic acid (C18:2n6)	1.00 (Ref)	0.92 (0.65, 1.30)	0.92 (0.65, 1.29)	1.01 (0.71-1.41)	0.95

\*Multivariable-adjusted RRs (95% CIs) were calculated for Q2-Q4 of the erythrocyte n-6 fatty acids using Q1 as the reference group. Model 3 was adjusted for age, sex, BMI, waist-hip ratio, physical activity, education, alcohol drinking, smoking, household income, family history of diabetes, total energy intake, fasting blood glucose and erythrocyte total n-3 PUFAs. Model 3a (n=2,707) included covariates in model 3 + additional dietary variables (dietary intake of dairy products, red and processed meat, fish, vegetable, and fruit, in quartiles). Model 3b (n=2,731) included covariates in model 3 + baseline total triglycerides and low-density lipoprotein cholesterol. Model 3c (n=2,731) included covariates in model 3 + prevalent coronary heart disease, treatment for hypertension and hyperlipidemia. *p* value for trend was calculated based on per quartile increase in the corresponding PUFA. Abbreviations: BMI, body mass index; CIs, confidence intervals; PUFAs, polyunsaturated fatty acids; Q, quartile; RRs, risk ratios.

	Model 2	1.00 (Ref)	0.89 (0.59, 1.33)	0.91 (0.61, 1.37)	0.92 (0.61, 1.38)	0.72
	Model 3	1.00 (Ref)	0.89 (0.59, 1.34)	1.02 (0.68, 1.53)	1.07 (0.71, 1.61)	0.58

\* Multivariable-adjusted RRs (95% CIs) were calculated for Q2-Q4 of the erythrocyte n-6 fatty acids using Q1 as the reference group. Covariates included in model 1 were age, sex, BMI and waist-hip ratio; model 2, model 1 + education, household income, smoking and alcohol drinking status, physical activity, total energy intake, family history of diabetes; and model 3, as model 2 + baseline erythrocyte total n-3 PUFAs and fasting glucose. *p* value for trend was calculated based on per quartile increase in the corresponding PUFA. Abbreviations: BMI, body mass index; CIs, confidence intervals; PUFAs, polyunsaturated fatty acids; Q, quartile; RRs, risk ratios.

**Table S13. Summary statistics of the mediation analysis for  $\alpha$ -diversity indicators\***

	<b>n</b>	<b>ACME</b>	<b><i>p</i></b>	<b>ADE</b>	<b><i>p</i></b>	<b>%</b>
Observed OTUs	1563	0.0011	0.006	0.14	0.01	7.9
Chao index	1563	0.00097	0.011	0.012	0.0093	7.1
Shannon's diversity index	1563	0.00098	0.005	0.012	0.01	7.1

\* Models were built to test whether the association between  $\gamma$ -linolenic acid and type 2 diabetes was mediated by gut microbial  $\alpha$ -diversity indices. The direct and indirect effects are calculated using the quasi-Bayesian Monte Carlo method with 2,000 simulations (R *{mediation}*).

Covariates included age, sex, BMI and waist-hip ratio, education, household income, smoking and alcohol drinking status, physical activity, total energy intake, family history of diabetes, baseline erythrocyte total n-3 polyunsaturated fatty acids and fasting glucose. Abbreviations: BMI, body mass index.

**Table S14. Association of erythrocyte n-6 fatty acid biomarkers with microbiota  $\beta$ -diversity (N=1,591) \***

Erythrocyte n-6 fatty acids	Genus scaled relative abundances				OTU scaled relative abundances			
	Df	F	R <sup>2</sup>	<i>p</i>	Df	F	R <sup>2</sup>	<i>p</i>
Linoleic acid (C18:2n6)	3	1.17962	0.00214	0.14	3	1.05695	0.002	0.31
$\gamma$ -linolenic acid ( $\gamma$ C18:3n6)	3	1.63964	0.00298	0.002	3	1.46483	0.003	0.001

Total n-6 PUFAs	3	1.36979	0.00249	0.03	3	1.21031	0.002	0.062

\* The dissimilarities in gut composition between quartiles of n-6 PUFA biomarkers ( $\beta$ -diversity) were assessed with PERMANOVA (R function `adonis {vegan}`, 999 permutations) based on the Bray-Curtis distance calculated at the genus and OTU level. Scaled (that is, divided by the standard deviation) relative abundances were used. The potential confounders included in the PERMANOVA were sequencing depth, sequencing batch, Bristol scale, age, sex, BMI, waist-hip ratio, education, household income, smoking status, alcohol drinking status, physical activity, total energy intake, and baseline erythrocyte total n-3 PUFAs. Abbreviations: BMI, body mass index, PUFAs, polyunsaturated fatty acids.

**Table S15. Results from Pairwise PERMANOVA analysis of  $\gamma$ -linolenic acid ( $\gamma$ C18:3n6) verses microbiota  $\beta$  diversity (N=1,591) \***

$\gamma$ -linolenic acid ( $\gamma$ C18:3n6)	Genus scaled relative abundances				OTU scaled relative abundances

\* Beta values (95% CIs) were calculated for Q2-Q4 of the dietary n-6 fatty acids intake using Q1 as the reference group.  $\alpha$ -diversity metrics were standardized to have mean 0 and SD 1 and then were modeled as responses in linear mixed models with technical confounders including sequencing depth and Bristol scale as fixed effects, and sequencing batch as random effect. Linear regression was conducted with the residuals of  $\alpha$ -diversity metrics as dependent variables and baseline quartiles of individual n-6 fatty acid biomarkers as independent variables. Covariates included age, sex, BMI and waist-hip ratio, education, household income,

smoking and alcohol drinking status, physical activity, total energy intake, baseline erythrocyte total n-3 PUFAs. Abbreviations: BMI, body mass index; CIs, confidence intervals; PUFAs, polyunsaturated fatty acids; Q, quartile.

**Table S21. Association of dietary n-6 fatty acid intake with microbiota  $\beta$ -diversity (N=1,591) \***

Dietary n-6 fatty acids	Genus scaled relative abundances			
	Df	F	R <sup>2</sup>	<i>p</i>
Linoleic acid (C18:2n6)	3	0.8891	0.00168	0.71
Arachidonic acid (C20:4n6)	3	1.5366	0.00285	0.006
Total n-6 PUFAs	3	0.7570	0.0014	0.937

\* The dissimilarities in gut composition between quartiles of dietary n-6 PUFA ( $\beta$ -diversity) were assessed with PERMANOVA (R function `adonis {vegan}`, 999 permutations) based on the Bray-Curtis distance calculated at the genus and OTU level. Scaled (that is, divided by the standard deviation) relative abundances were used. The potential confounders included in the PERMANOVA were sequencing depth, sequencing batch, Bristol scale, age, sex, BMI, waist-hip ratio, education, household income, smoking status, alcohol drinking status, physical activity, total energy intake, and baseline erythrocyte total n-3 PUFAs. Abbreviations: BMI, body mass index, PUFAs, polyunsaturated fatty acids.
