A logistic regression model was used to analyze the relative odds and their 95% confidence intervals for diabetic complications and all-cause mortality according to each pancreatic disease in the DEP group. Odds ratios were adjusted for sex, age, BMI, FPG, LDL-cholesterol, alcohol consumption, smoking status, medical coverage, systolic BP, triglyceride, eGFR, and CCI as previously defined as Model 2 OR. Diabetes without prior pancreatic disease described as type 2 diabetes was used as a reference group. N/A indicates insufficient number of events to estimates odds of the outcome.

Type 2 diabetes=diabetes without prior pancreatic disease. PPDM-A=post-acute pancreatitis diabetes mellitus. PPDM-C=post-chronic pancreatitis diabetes mellitus. PCRD=pancreatic cancer-related diabetes. CFRD=cystic fibrosis-related diabetes. OR=Odds ratio. BMI=body mass index. N/A=not available. FPG=fasting plasma glucose. LDL=low-density lipoprotein. **Supplementary Figure S1. Flowchart of patient selection**

**Supplementary Figure S2. Sensitivity analysis for insulin use at each time point between DEP and type 2 diabetes excluding patients who initiated insulin within 6 months since diagnosis of diabetes**

We performed a sensitivity analysis for the cumulative insulin use by eliminating the number of patients who had started insulin within 6 months since diagnosis of diabetes. We nullified insulin use for first 6-month period after the index date to exclude transient insulin use for acute hyperglycemia in patients with first diagnosis of diabetes. Therefore insulin use for the first 6 months had a value of zero on the y-axis, resulting in a horizontal line with slope of zero. And if subjects continue to use insulin even after 6 months from the index date, it was recognized as true insulin use. The table is the number of patients at risk over time ( $p < 0.0001$  by log-rank test). DEP=diabetes following pancreatic disease. Type 2 diabetes=diabetes without prior pancreatic disease.

**Supplementary Figure S3. Subgroup analysis of ORs for diabetic complications and all-cause mortality of DEP compared to type 2 diabetes by insulin regimen**

Forest plots of the odds ratios and 95% confidence intervals for diabetic complications and all-cause mortality according to insulin regimen were analyzed by logistic regression models. Each insulin regimen consisted of basal insulin (intermediate, long acting insulin) alone, prandial insulin (short, rapid acting insulin) alone, and combination of basal and prandial insulin. Diabetes without prior pancreatic disease described as type 2 diabetes was used as a reference group. OR is the odds ratio adjusted for sex, age, BMI, FPG, LDL-cholesterol, alcohol consumption, smoking status, medical coverage, systolic BP, triglyceride, eGFR, and CCI.

DEP=diabetes following pancreatic disease. Type 2 diabetes=diabetes without prior pancreatic disease. OR=Odds ratio. CI=Confidence interval. BMI=body mass index. FPG=fasting plasma glucose. LDL=low-density lipoprotein. BP=blood pressure. eGFR=estimated glomerular filtration rate. CCI=Charlson comorbidity index.
