## Appendix 1 The selection process of study population

### 1) Merge datasets to obtain most recent information

Three DCS dataset (A dataset with subgroup indicators as the output of previous published work (1) [DCS\_Clusters\_JC], an updated DCS dataset with observations over the period 1998 to 2019 [DCS\_1998\_2019\_28042020e], and a dataset containing C peptide information [DCS\_C peptide]) were merged and filtered, see Figure 1.1.

### 2) Adjust diabetes duration

The diabetes duration was adjusted according to age at diagnosis and current age, see Figure 1.2.

Figure 1.1 Flow chart depicting merging of different datasets

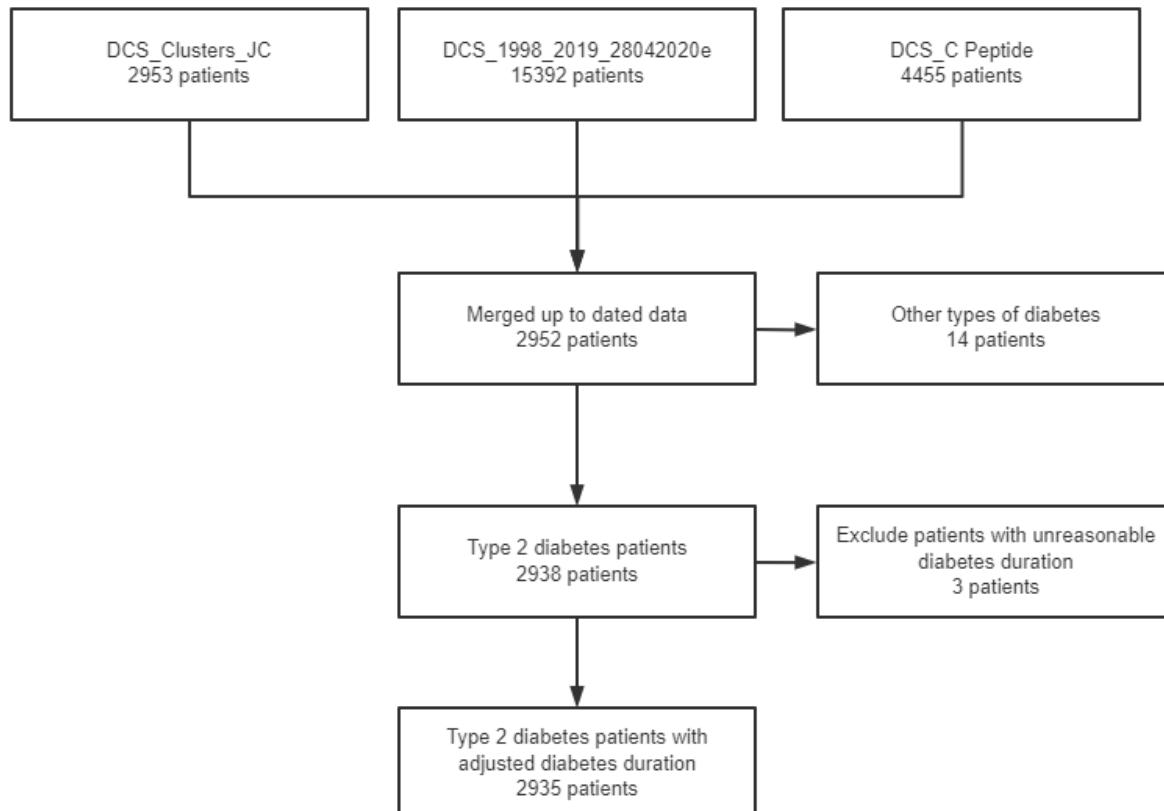

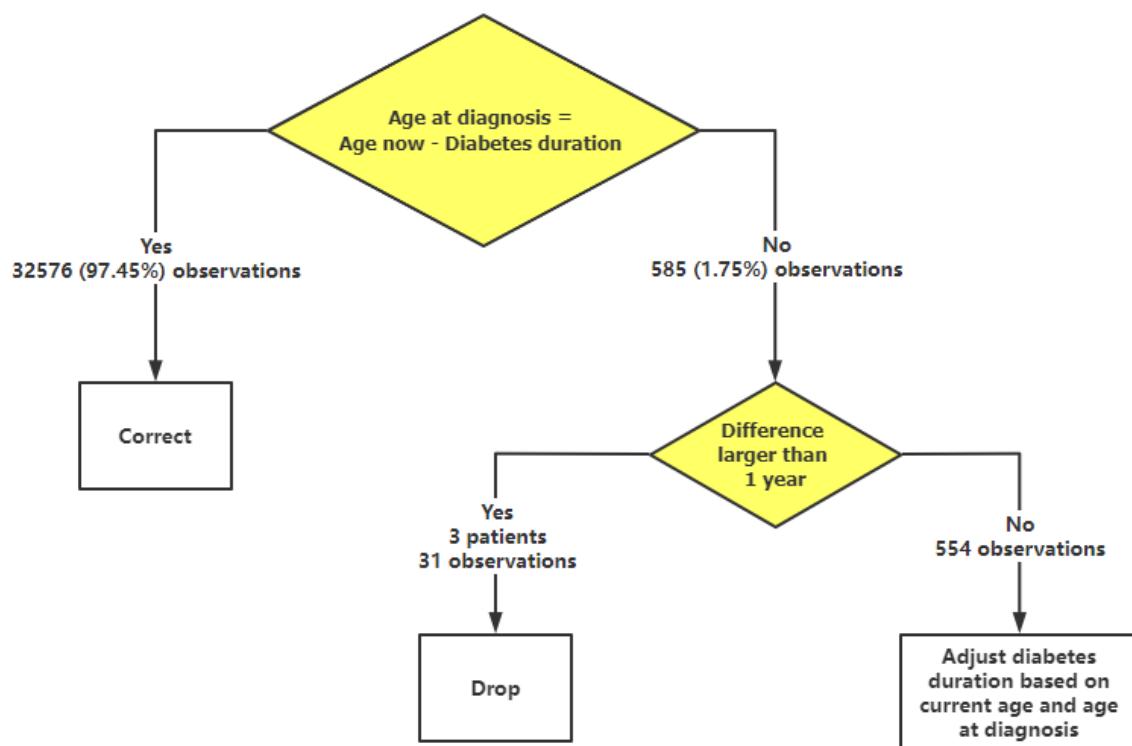

Figure 1.2 Flow diagram of adjusting diabetes duration

Appendix 2 Model input

Table 2.1 Treatment targets used in scenario analyses for treat-to-target strategies

<b>Guideline Based Treatment Target</b>			
HbA1c (%, mmol/mol)	BMI (kg/m <sup>2</sup> )	LDL (mmol/liter)*	
7% (53 mmol/mol)	25 (kg/m <sup>2</sup> )	Very high risk (SCORE≥10%)	1.4 mmol/L
		High risk (10%>SCORE≥5%)	1.8 mmol/L
		Moderate risk (5%>SCORE≥1%)	2.6 mmol/L
		Low risk (1%>SCORE)	3 mmol/L

\* An individualized target was applied for LDL based on each patient's cardiovascular risk calculated by Systematic Coronary Risk Estimation (SCORE) using age, sex, smoking status, total cholesterol and SBP (2; 3).

Table 2.2 The input of United Kingdom Prospective Diabetes Study Outcomes Model version 2 (UKPDS-OM2)

Required input in UKPDS-OM2			
	Baseline	Follow up	Extrapolation over life time
Demographic characteristics	Ethnicity		
	Gender		
	Age now		
	Duration of diabetes		
	Weight	Weight	Linear dynamic model
	Height		
Risk factor values	AF (Y/N)*	AF (Y/N)*	Regression model* and carry forward
	PVD (Y/N)*	PVD (Y/N)*	Regression model* and carry forward
	Current smoker (Y/N)	Current smoker (Y/N)	Carry forward
	Albuminuria (Y/N)	Albuminuria (Y/N)	Carry forward
	HDL	HDL	Carry forward
	LDL	LDL	Linear dynamic model
	Systolic BP	Systolic BP	Carry forward
	HbA1c	HbA1c	Linear dynamic model
	Heart rate*	Heart rate*	Regression model* and carry forward
	White blood cells*	White blood cells*	Regression model* and carry forward
	Haemoglobin*	Haemoglobin*	Regression model* and carry forward
	eGFR	eGFR	Linear dynamic model
Pre-existing events †	IHD		
	Heart failure		
	Amputation		
	Blindness in one eye		
	Renal failure		
	Stroke		
	MI		
	Ulcer		

AF, Atrial Fibrillation; PVD, Peripheral Vascular Disease; eGFR, estimated Glomerular Filtration Rate; IHD, Ischemic Heart Disease; MI, Myocardial Infarction

\* The value is completely missing in our dataset. We used available risk factors (e.g. BMI, HbA1c) to impute them. For more information, please refer to Appendix 3.

† Details related to ICD and other characteristics of pre-existing events were listed in Table 3.1. The duration of pre-existing event (years) was measured as (baseline measurement date - event date) (days)/365, and rounded to the nearest integer.

Table 2.3 Quality of life mean estimates and costs\* used in the scenario's analyses. (US costs expressed in \$2019 prices and UK costs expressed in £2019 prices)

<b>Category</b>	<b>US†</b>		<b>UK†</b>

<i>In the year of fatal event</i>				
IHD	\$25,716	Ward 2014 (8)	£4,715-£7,559*	Alva 2015(7)
MI	\$67,811	Ward 2014 (8)	£2,341-£8,474*	Alva 2015(7)
Heart failure	50% of non-fatal cost			50% of non-fatal cost
Stroke	\$14,271	Ward 2014 (8)	£2,015-£3,352*	Alva 2015(7)
Amputation	\$25,716	Non-fatal minus 50% of cost	£5,255-£8,124*	Non-fatal minus 50% of cost
	\$10,861	subsequent years	£11,428-£16,561*	50% of cost subsequent years
Renal failure	\$43,077	50% of non-fatal cost	£11,650	50% of non-fatal cost
<i>In subsequent years§</i>				
IHD	\$2,287	Ward 2014 (8)	£1,616-£5,050*	Alva 2015(7)
MI	\$2,287	Ward 2014 (8)	£1,586-£4,843*	Alva 2015(7)
Heart failure	\$2,287	Ward 2014 (8)	£2,197-£5,864*	Alva 2015(7)
Stroke	\$18,670	Ward 2014 (8)	£1,659-£5,034*	Alva 2015(7)
Amputation	\$0	Ward 2014 (8)	£3,209-£6,934*	Alva 2015(7)
Blindness in one eye	\$3,438	Ward 2014 (8)	£1,098-£3,177*	Alva 2015(7)
Renal failure	\$86,154	Ward 2014 (8)	£23,300	NHS Blood and Transplant 2009 (9)
Ulcer	\$2,579	Ward 2014 (8)	£1,179	Kerr 2014 (10)

\* Costs varied by sex and age group (up to 50, 51-60, 61-70, 71-80, 81+).

† US costs include medications, outpatient consultations, emergency department visits and inpatient stays(8). UK costs include non-inpatient contacts (e.g. general practitioner, nurse, hospital eye clinic, etc.) and inpatient stay(7).

‡ US diabetes management costs obtained from ADA 2018 excluding costs of complications. UK diabetes management costs obtained from UKPDS and concern costs in the absence of complications(7). IGT costs estimated by applying ratio of IGT and diabetes costs per individual from Khan 2007(11) for the US setting (0.74) and DPP(12) for the UK setting (0.77).

§ In the US analysis, IGT/diabetes management costs (\$6,762/\$9,158) were added to costs of non-fatal events in the year of the event and in subsequent years. In the UK analysis, management costs were already included in the costs of complications and no further costs were added to them.

Table 2.4 The effect of hypothetical treatment on risk factors of each RHAPSODY data-driven subgroup

		<b>Year 1</b>	<b>Year 2</b>	<b>Year 3</b>	<b>Year 4</b>	<b>Year 5</b>

Figure 2.1 Progression of clinical parameters by RHAPSODY data-driven subgroups' mean over time since diagnosis

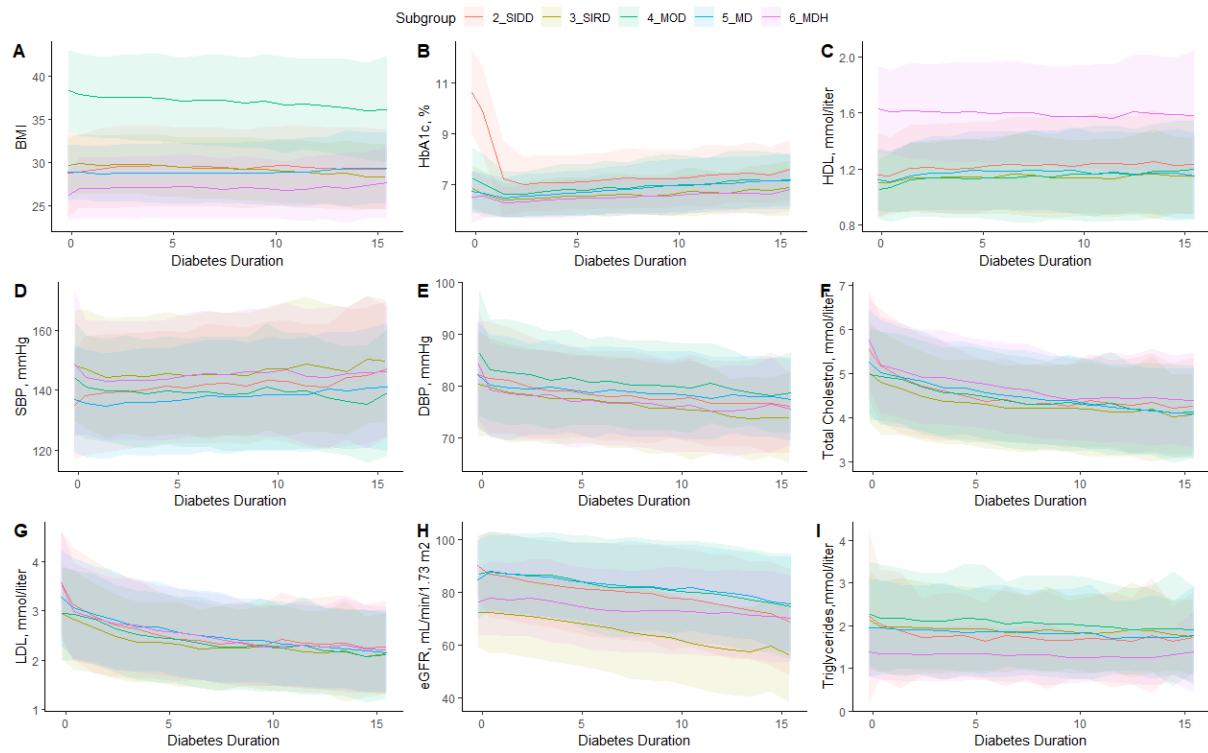

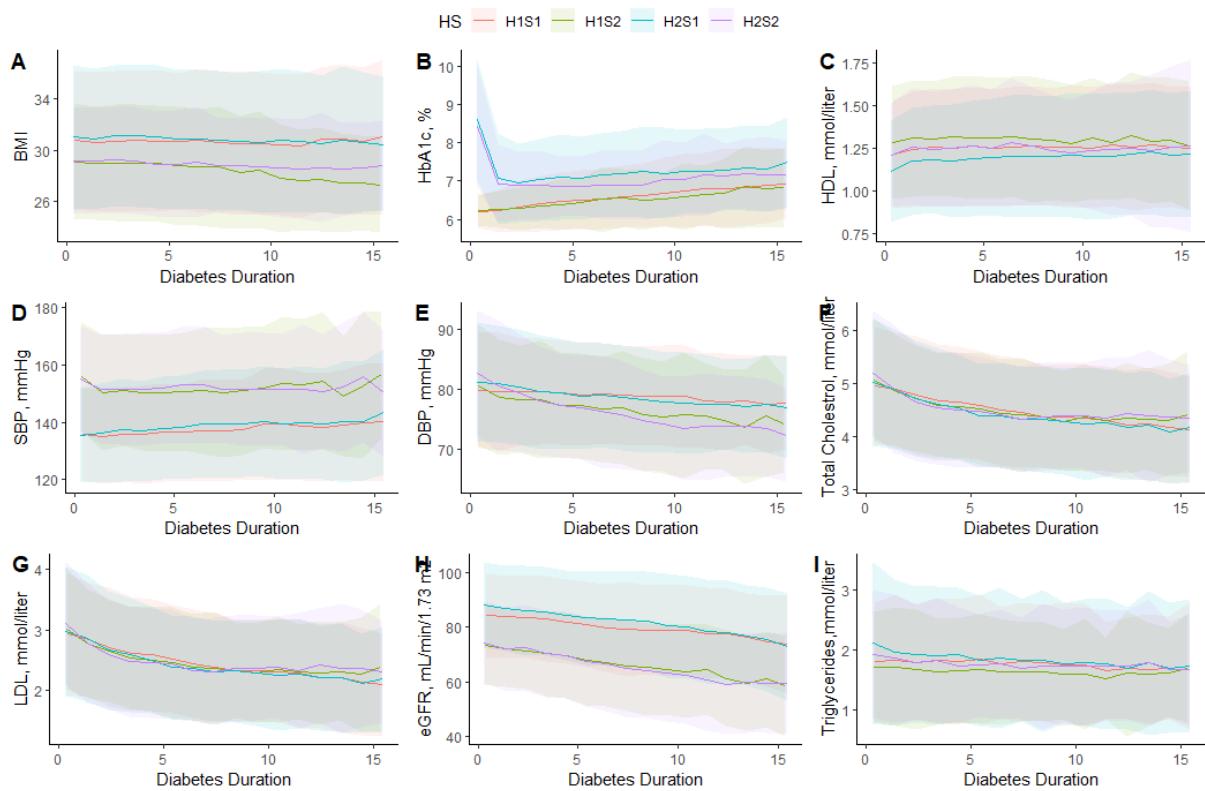

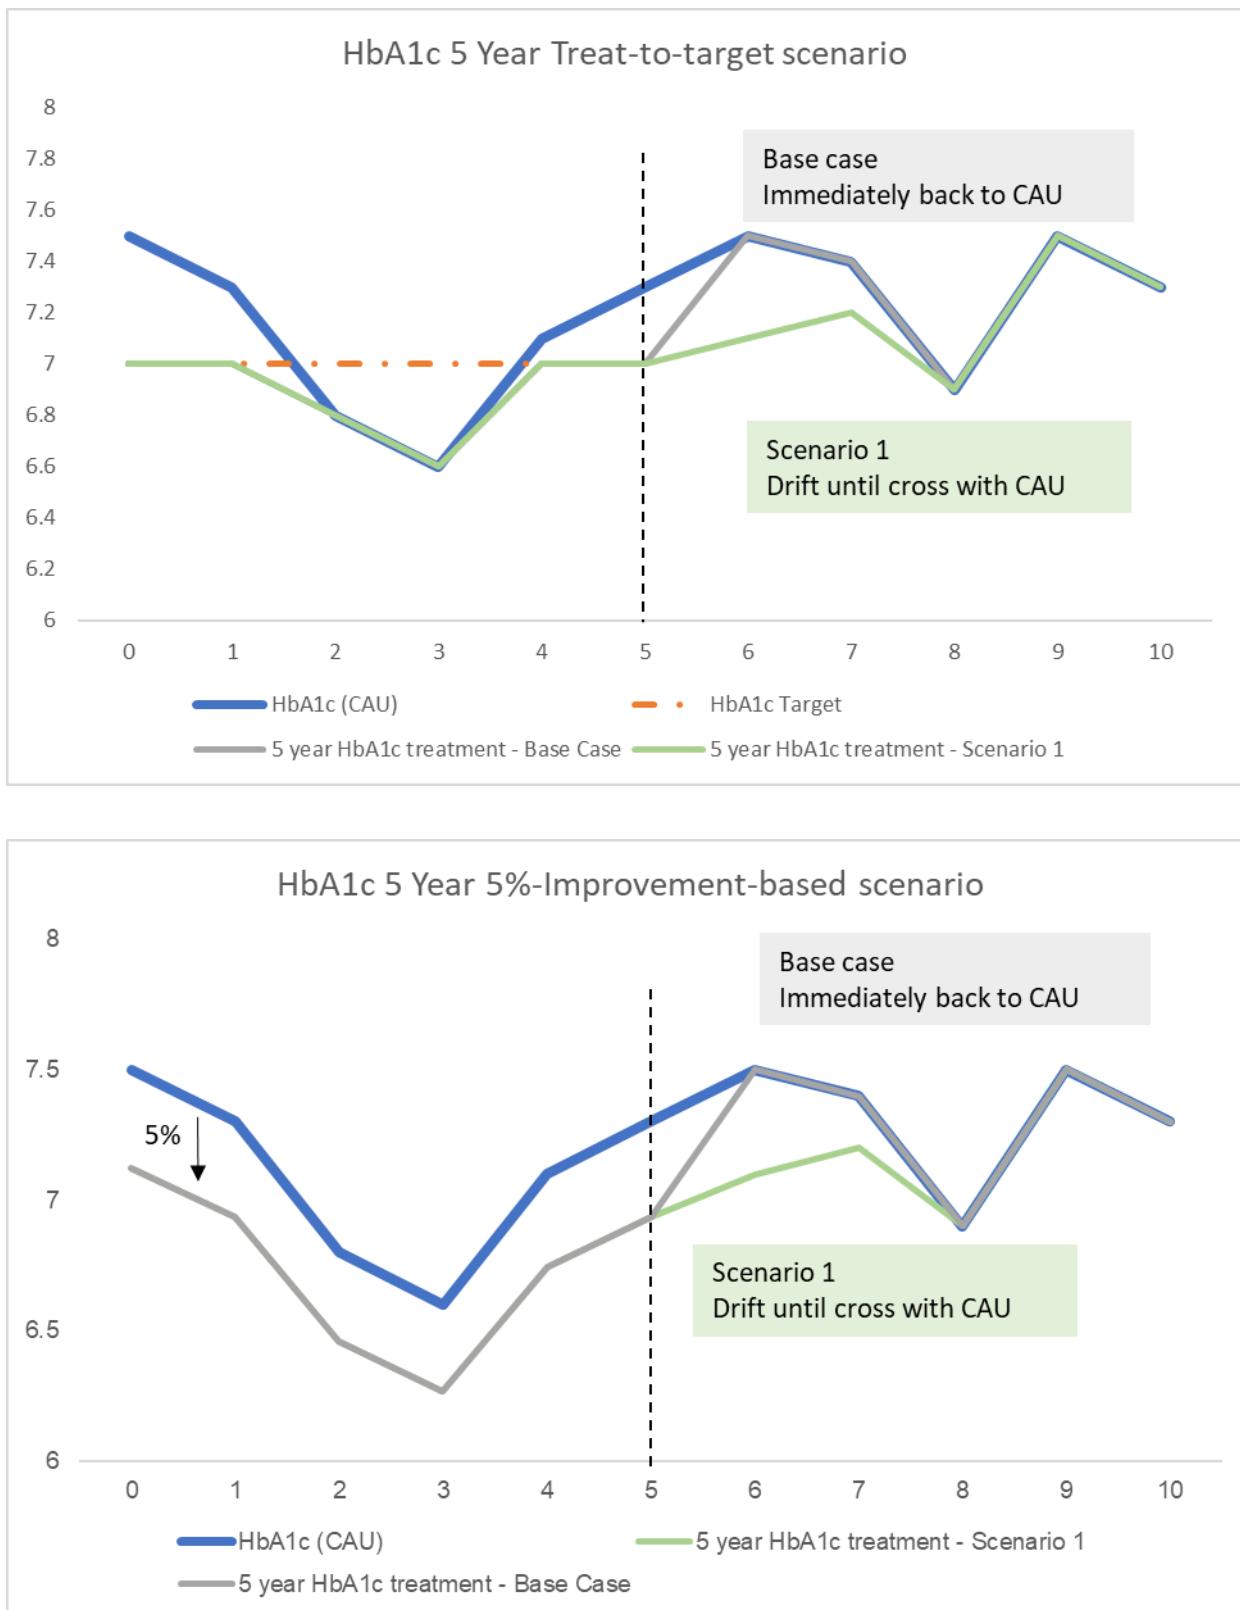

Figure 2.2 Progression of clinical parameters by risk-driven subgroups' mean over time since diagnosis

The data are represented as annually diabetes duration mean values (solid line)  $\pm$  standard deviation (shaded areas) of each risk-driven subgroup.

Figure 2.3 Graphical representations of scenario assumptions

CAU, Care-as-usual

### Appendix 3 Data cleaning

- 1) To avoid survival bias, as the baseline we used observed patient-level data from each individual's first observation after 2008 (the time of obtaining informed consent).
- 2) Missing ethnicities (4.97%) was set to "White", reflecting the most frequently observed ethnicity (92.13%).
- 3) Micro or macroalbuminuria was defined as urinary microalbumin (mg/liter) >50 (mg/liter).
- 4) Missing diabetes duration and age values were interpolated between two known values over time, and extrapolated by adding 1 to the last observed value annually.
- 5) Missing values of first observation of HbA1c, LDL, weight, eGFR, atrial fibrillation, peripheral vascular disease, smoking status, albuminuria, HDL, SBP, heart rate, white blood cells, and hemoglobin were imputed by the mean at first observation of each subgroup.
- 6) Missing values for risk factors over time were imputed as described in Table 2.2 by linear dynamic models (for HbA1c, LDL, weight, and eGFR; see details in Appendix 4) or carried forward from last observed value (for atrial fibrillation, peripheral vascular disease, smoking status, albuminuria, HDL, SBP, heart rate, white blood cells, and hemoglobin).
- 7) For individuals with multiple records of the same variable within a single year, the first observation was applied.
- 8) Variables which were not recorded in the registry (Table 2.2) but were required by the UKPDS-OM2 were imputed based on existing DCS data and published equations (13).
- 9) Events were coded according to the International Stratification of Diseases, Injuries and Causes of Death, ninth revision (ICD9) (14) and defined by self-report, which was partly verified by the electronic patient records from the regional hospital and GP (15). Furthermore, Sims (16), and retinopathy grades from EURODIAB scale (17) were also applied as in Table 3.1. Amputation was identified for patients identified as Sims=3. The duration of pre-existing event (years) was measured by (baseline measurement date - event date) (days)/365, and rounded to the nearest integer.

Table 3.1 Characteristics of pre-existing events in UKPDS OM2 input for DCS-dataset

	<b>ICD 9</b>	<b>Additional information</b>
<b>Ischemic heart disease</b>	411-414	
<b>Heart failure</b>	428	
<b>Amputation</b>	84.10, 84.11-84.14, 84.15-84.18, 84.3, 84.4; except: 800-959 all diagnosis fields	Sims=3 (Exclude patients identified as Ulcer)
<b>Blindness in one eye</b>	369	Score=5
<b>Renal failure</b>	586	
<b>Stroke</b>	430-434 and 436 (non-fatal) & Fatal 430-438	
<b>Myocardial infarction</b>	410&798	
<b>Ulcer</b>	707.10, 707.14	

#### Appendix 4      The method of imputing risk-factor progression beyond observed values

Linear dynamic models were estimated on the time paths of HbA1c, LDL, weight and eGFR for each subgroup, to allow for imputation of missing data and extrapolation of risk factor trajectories where data were censored. Following recent research (18), these models included the value of the risk factor in the previous year, the number of years since diagnosis (in log form for improved fit), value of the risk factor at baseline, sex, an indicator for first year of follow-up (to capture treatment effect following diagnosis), and an interaction term for first year of follow-up and risk factor at baseline (to capture different treatment effects conditional on initial risk factor value). Missing data (Table 4.1) were imputed by Multivariate Imputation by Chained Equations when estimating the linear dynamic models, and results were combined in 25 imputed data sets using the packages *mice* and *mitools* in R 4.1.0 (19-21). Models were estimated for each clustered subgroup and each risk-driven subgroup. Results were listed in Table 4.2-Table 4.5 and Figure 4.1-Figure 4.8.

Table 4.1 Missing data

Data	Number of missing	Proportion of missing
Length	1	0.00%
BMI	207	0.62%
Weight	209	0.63%
SBP	262	0.78%
DBP	264	0.79%
Total cholesterol	300	0.90%
Triglyceride	304	0.91%
Creatinine	316	0.95%
Cholesterol ratio	316	0.95%
HDL	317	0.95%
HbA1c	323	0.97%
eGFR	324	0.97%
LDL	510	1.53%
Fast glucose	532	1.59%
Smoking status	593	1.78%

Predicted value based on last observed/predicted (blue line) denotes the values extrapolated based on baseline value and available data observed during follow-up.

Figure 4.8 The graphs for goodness-of-fit over time for LDL of each risk-driven subgroup

Grey area indicated 95% confidence interval of observed data.

Observed value (red line) denotes the observational data.

Predicted value based on baseline only (green line) denotes the values extrapolated based on only baseline value.

Predicted value based on last observed/predicted (blue line) denotes the values extrapolated based on baseline value and available data observed during follow-up.

## Appendix 5 The method of calculating annual maximum cost-effective price

First, note that the definition of cost-effectiveness thresholds implies that

$$\frac{\Delta \text{Complication cost} + \text{Maximum discounted intervention price}}{\Delta \text{QALY}} = \text{Cost - effective threshold} \quad (1)$$

Also note that the maximum discounted intervention price can be calculated as:

$$\text{Maximum discounted intervention price} = \sum_{k=1}^i \frac{\text{Average year } k \text{ survival rate} * \text{Maximum annual price}}{(1 + \text{discounting factor})^{k-1}} \quad (2)$$

Now, combine equation (1) and (2) to obtain (3) for an  $i$  year hypothetical treatment:

$$\text{Maximum annual price} = \frac{\Delta \text{QALY} * \text{Cost - effective threshold} - \Delta \text{Complication cost}}{\sum_{k=1}^i \frac{\text{Average year } k \text{ survival rate}}{(1 + \text{discounting factor})^{k-1}}} \quad (3)$$

where

$$\text{Average year } k \text{ survival rate} = \text{mean}((1 - \sum_{j=1}^k \text{death rate}_{\text{year } j}) + 0.5 * \text{death rate}_{\text{year } k})$$

Note:

$\Delta$  denotes increments between hypothetical treatment scenario and care-as-usual scenario.

$i$  denotes the duration of hypothetical treatment scenario (in years), which is five-year in the base case.

QALYs, quality-adjusted life years.

Discounting factor is either 3% in U.S. setting or 3.5% in U.K. setting.

Mean() is averaging across all patients.

Appendix 6 Baseline characteristics

Table 6.1 Baseline simulation characteristics of data-driven subgroups and risk-driven subgroups

	RHPSONDY Data-driven subgroups					Risk-driven subgroups					
	RHAP-SIDD	RHAP-SIRD	RHAP-MOD	RHAP-MD	RHAP-MDH	p	H1S1	H1S2	H2S1	H2S2	p

Frequencies (percentage) for categorical variables, or mean (standard deviation) for continuous variables. Chi-square tests were applied to check for significant differences between groups.

Simulation baseline for each individual was set as the landmark of the date of participation in the biobank sample around 2008 to avoid survival bias.

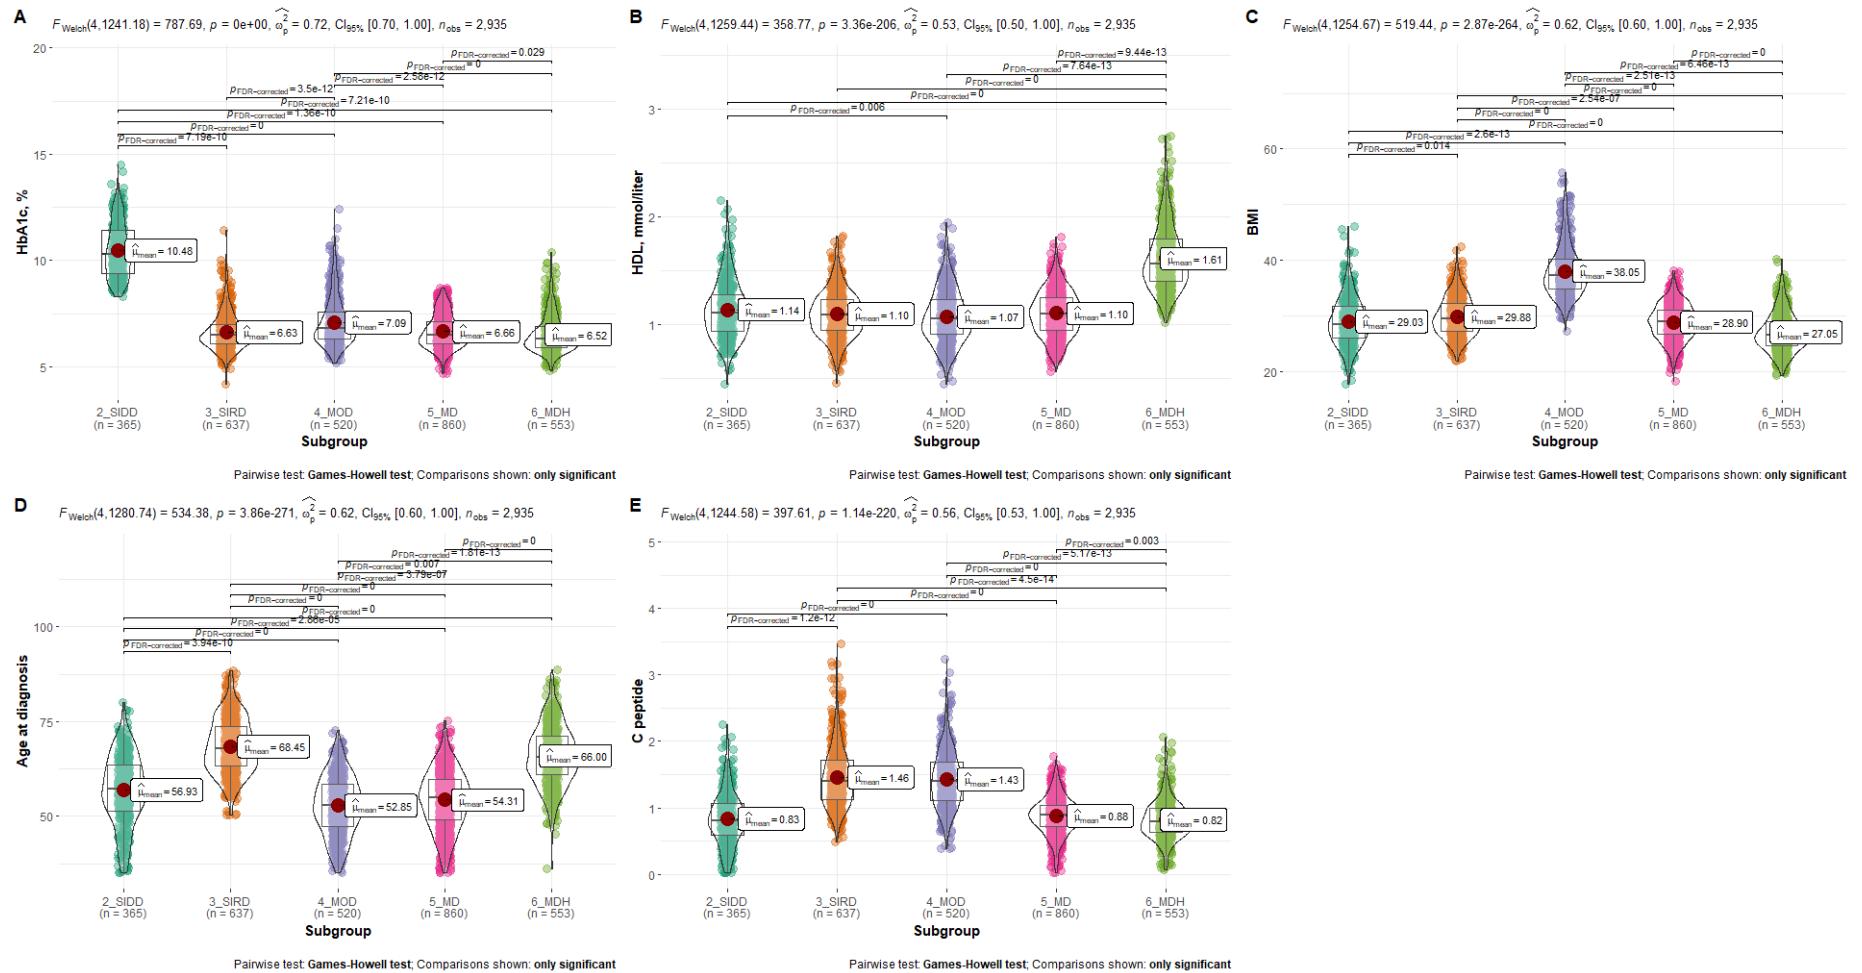

Figure 6.1 Violin graphs and pairwise comparisons of baseline clustering indicators of risk-driven subgroups

The Games-Howell test was applied to enable pairwise comparison and p values were adjusted by using Benjamini-Hochberg correction to account for false discovery rate. P-values below 0.05 were considered statistically significant.

These are the baseline characteristics at diagnosis, rather than the baseline simulation characteristics.

Figure 6.2 Violin graphs and pairwise comparisons of baseline clustering indicators of RHAPSODY data-driven subgroups

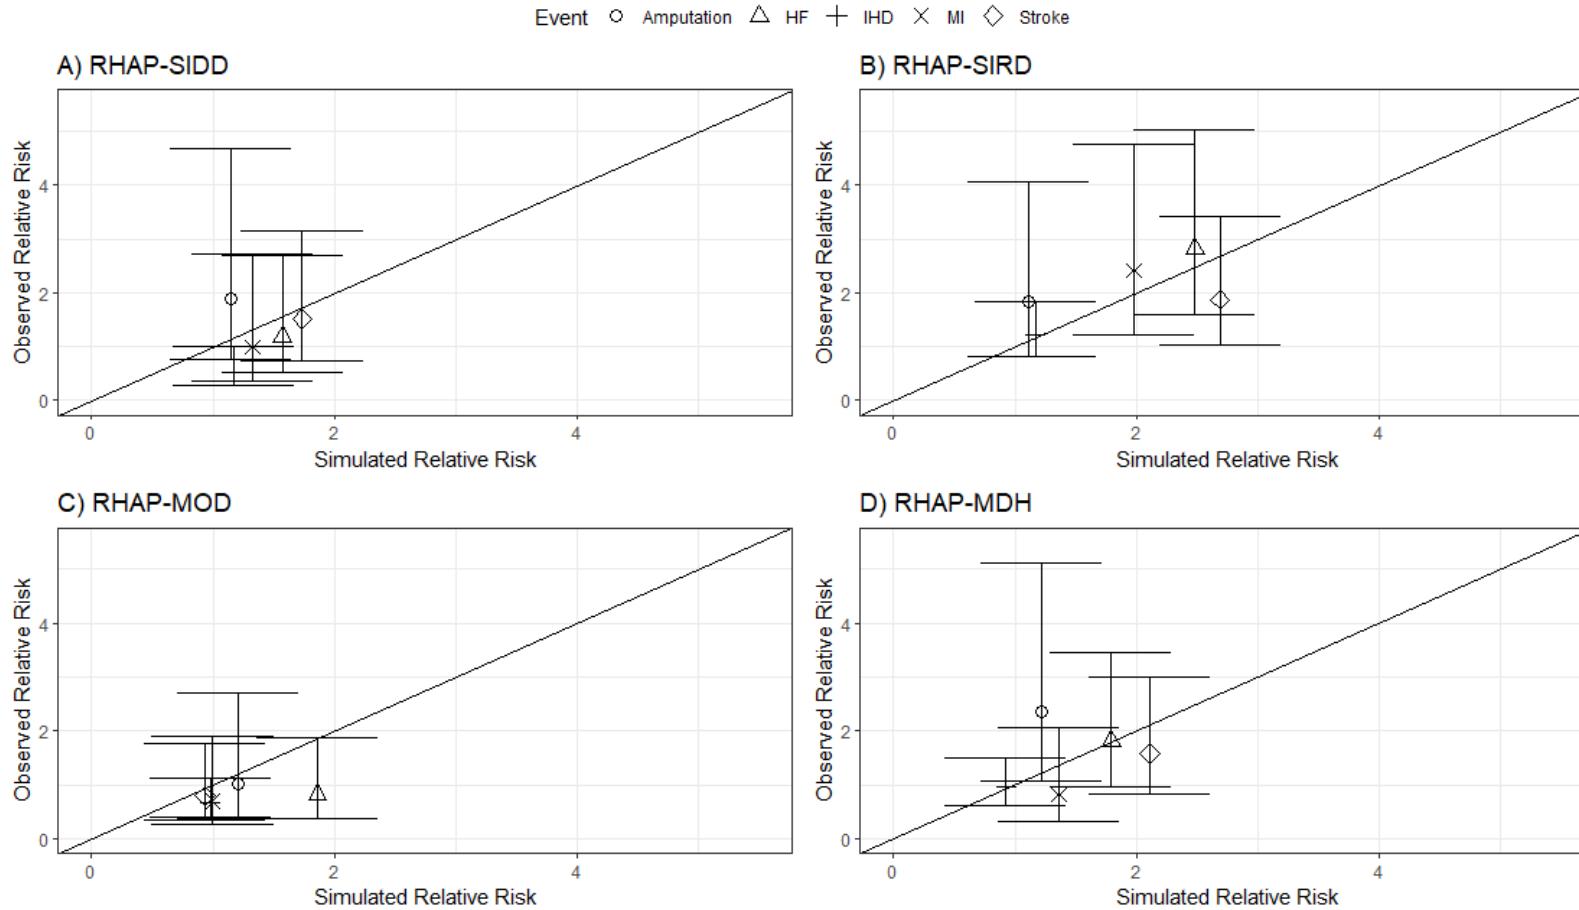

The Games-Howell test was applied to enable pairwise comparison and p values were adjusted by using Benjamini-Hochberg correction to account for false discovery rate. P-values below 0.05 were considered statistically significant.

These are the baseline characteristics at diagnosis, rather than the baseline simulation characteristics.

Appendix 7 Model validation

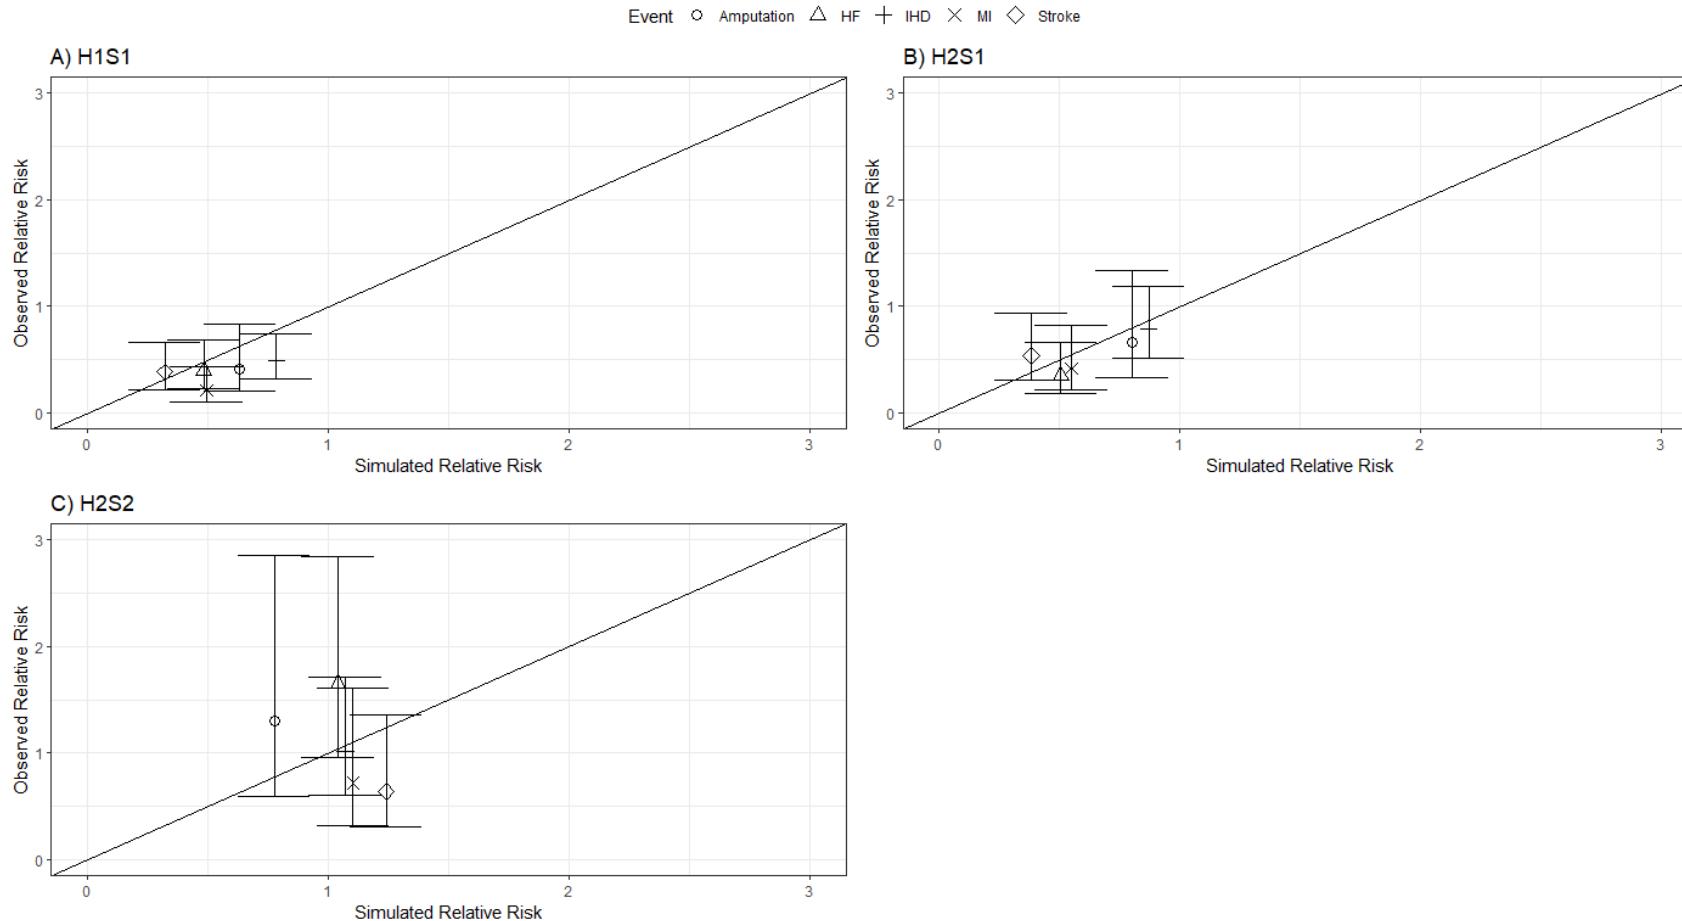

Figure 7.1 Model validation of subgroup-wise differences of relative risks in 5 years of simulation for RHAPSODY data-driven subgroups

**The comparision of relative risks in the 5 years of simulation (Reference group is RHAP-MD)**

The 45-degree line indicates perfect calibration (observations equals to simulations). The closer the point is to the 45-degree line, the better the model's prediction. The error bar indicates the 95% confidence interval of observed relative risks, and if simulated relative risks fit within the interval (i.e., the error bar crossed with the 45-degree line), we considered it as a valid prediction.

Figure 7.2 Model validation of subgroup-wise differences of relative risks in 5 years of simulation for risk-driven subgroups  
**The comparision of relative risks in the 5 years of simulation (Reference group is H1S2)**

The 45-degree line indicates perfect calibration (observations equals to simulations). The closer the point is to the 45-degree line, the better the model's prediction. The error bar indicates the 95% confidence interval of observed relative risks, and if simulated relative risks fit within the interval (i.e., the error bar crossed with the 45-degree line), we considered it as a valid prediction.

\*Overall refers to a homogenous type 2 diabetes group. (Results were generated based on extrapolations of subgroup-specific linear dynamic models and summarized by subgroup information. The overall result is summarized by the assumption that every individual was within this homogenous type 2 diabetes group. Each extrapolation from either RHAPSODY data-driven subgroups' or risk-driven subgroups' linear dynamic models led to an overall result, and the final overall result was taken as the average value).

†Range is defined as the maximum – minimum of the mean maximum annual cost-effective price of intervention or incremental QALY.

Range†	3.94	0.61	0.39	0.57	0.09	0.07

\* Overall was defined as the average result, indicating the result of calculating group-wise simulation outcome altogether as a homogenous type 2 diabetes group. (Average values of results based on three extrapolations of linear dynamic models estimated from Ahlqvist's and RHAPSODY data-driven subgroups and risk-driven subgroups were applied.)

†Range was defined as the maximum – minimum of the mean maximum annual cost-effective price of intervention or incremental QALYs. To compare the value of RHAPSODY data-driven subgroups versus risk-driven subgroups, the range between subgroups was considered, with a wider range indicating a greater ability to differentiate between subgroups.

\*Overall refers to a homogenous type 2 diabetes group. (Results were generated based on extrapolations of subgroup-specific linear dynamic models and summarized by subgroup information. The overall result is summarized by the assumption that every individual was within this homogenous type 2 diabetes group. Each extrapolation from either Ahlqvist's data-driven subgroups, RHAPSODY data-driven subgroups' or risk-driven subgroups' linear dynamic models led to an overall result, and the final overall result was taken as the average value).

†Range is defined as the maximum – minimum of the mean maximum annual cost-effective price of intervention or incremental QALY.

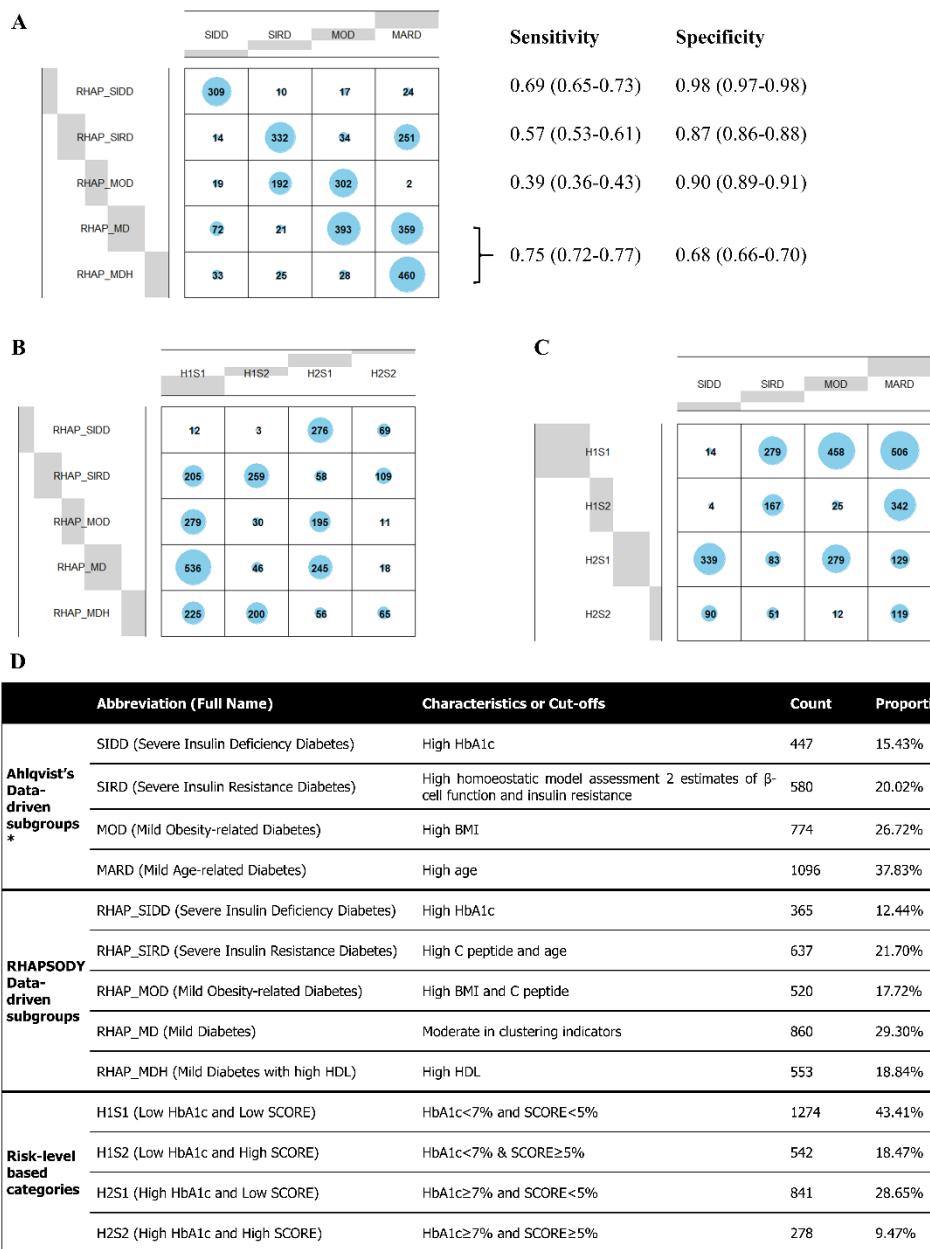

Table 10.9 Outcomes of five-year guideline-based and 5%-improvement based intensive management targeting HbA1c, BMI and LDL, and targeting only HbA1c respectively compared to care-as-usual by subgroups in U.K. setting

		Treat-to-target hypothetical intensive management				5%-Improvement-based hypothetical intensive management			
		HbA1c		HbA1c+LDL+BMI		HbA1c		HbA1c+LDL+BMI	
		Max annual price of intervention (£)	Δ QALYs vs CAU	Max annual price of intervention (£)	Δ QALYs vs CAU	Max annual price of intervention (£)	Δ QALYs vs CAU	Max annual price of intervention (£)	Δ QALYs vs CAU

The overall result is summarized by the assumption that every individual was within this homogenous type 2 diabetes group. Each extrapolation from either Ahlqvist's data-driven subgroups, RHAPSODY data-driven subgroups' or risk-driven subgroups' linear dynamic models led to an overall result, and the final overall result was taken as the average value).

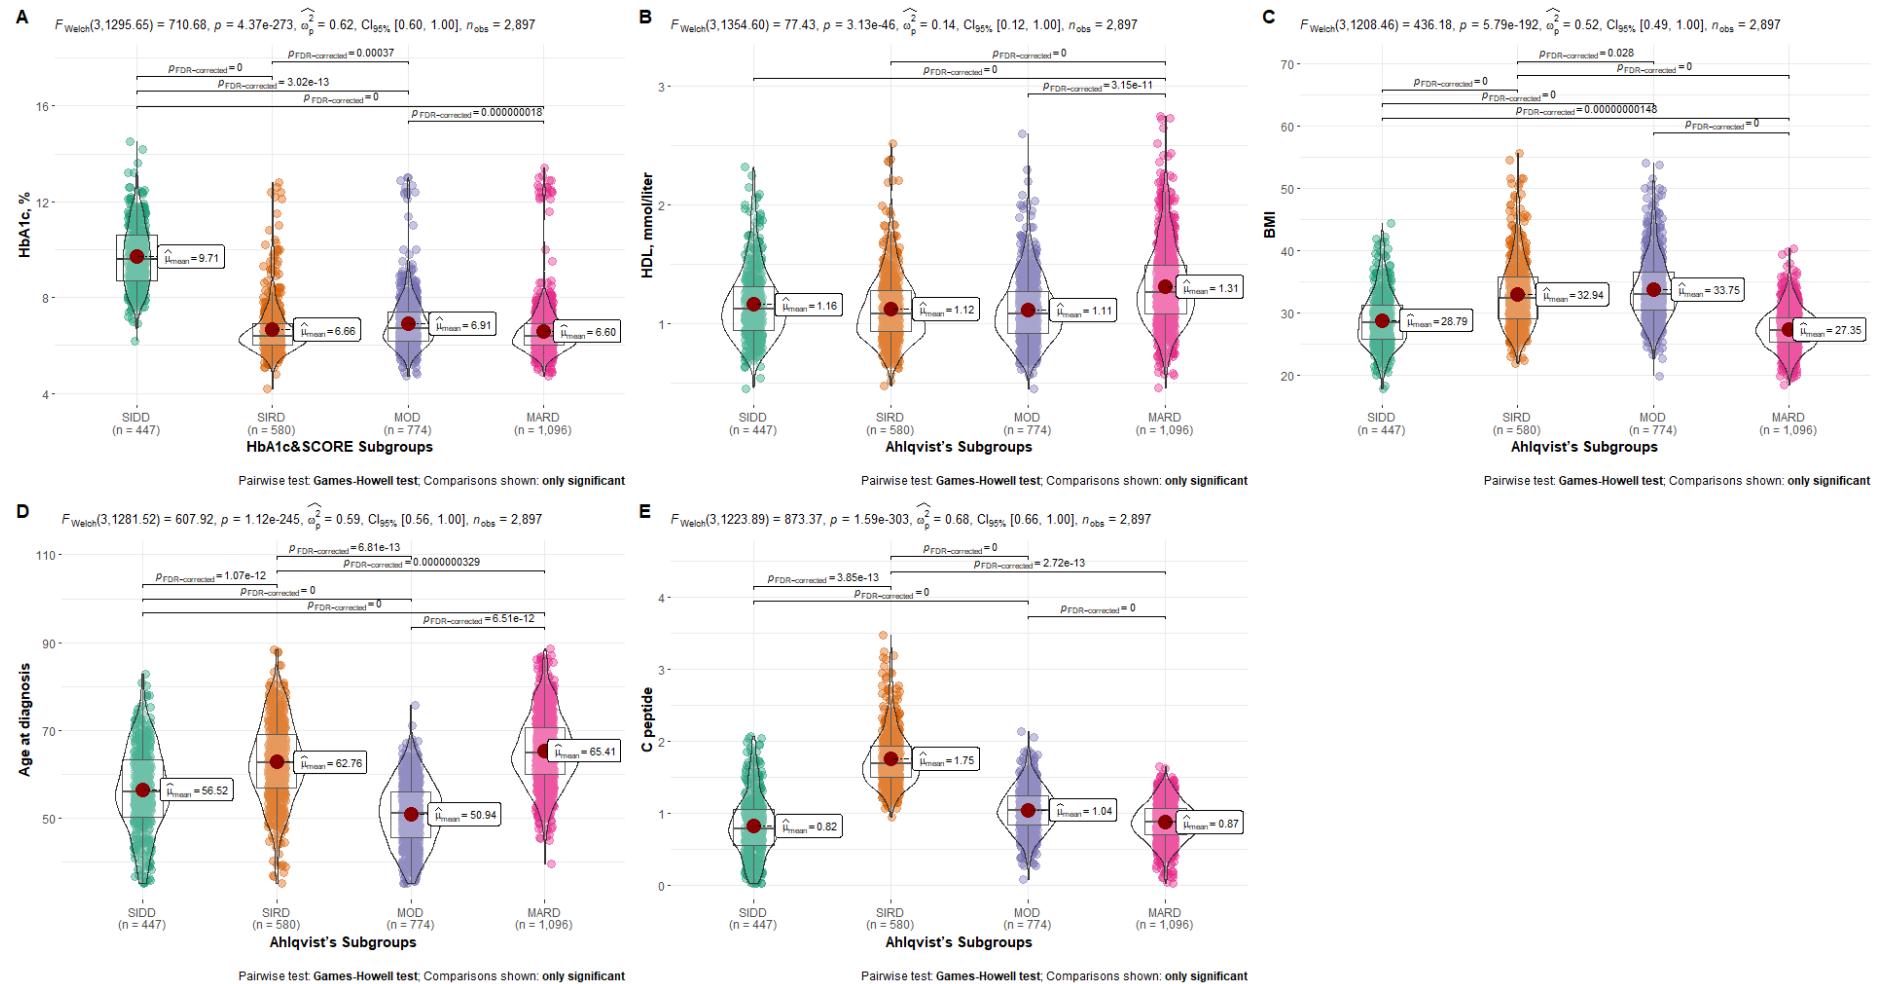

†Range is defined as the maximum – minimum of the mean maximum annual cost-effective price of intervention or incremental QALY.

Figure 10.1 Comparisons among subgroups defined by different methodology

\*For assigning Ahlqvist's subgroups Data-driven subgroups, there were 38 individuals less in total compared to RHAPSODY data-driven subgroups and risk-level based categories due to the missing of fasting glucose information which is required in the homoeostatic model assessment 2 estimates

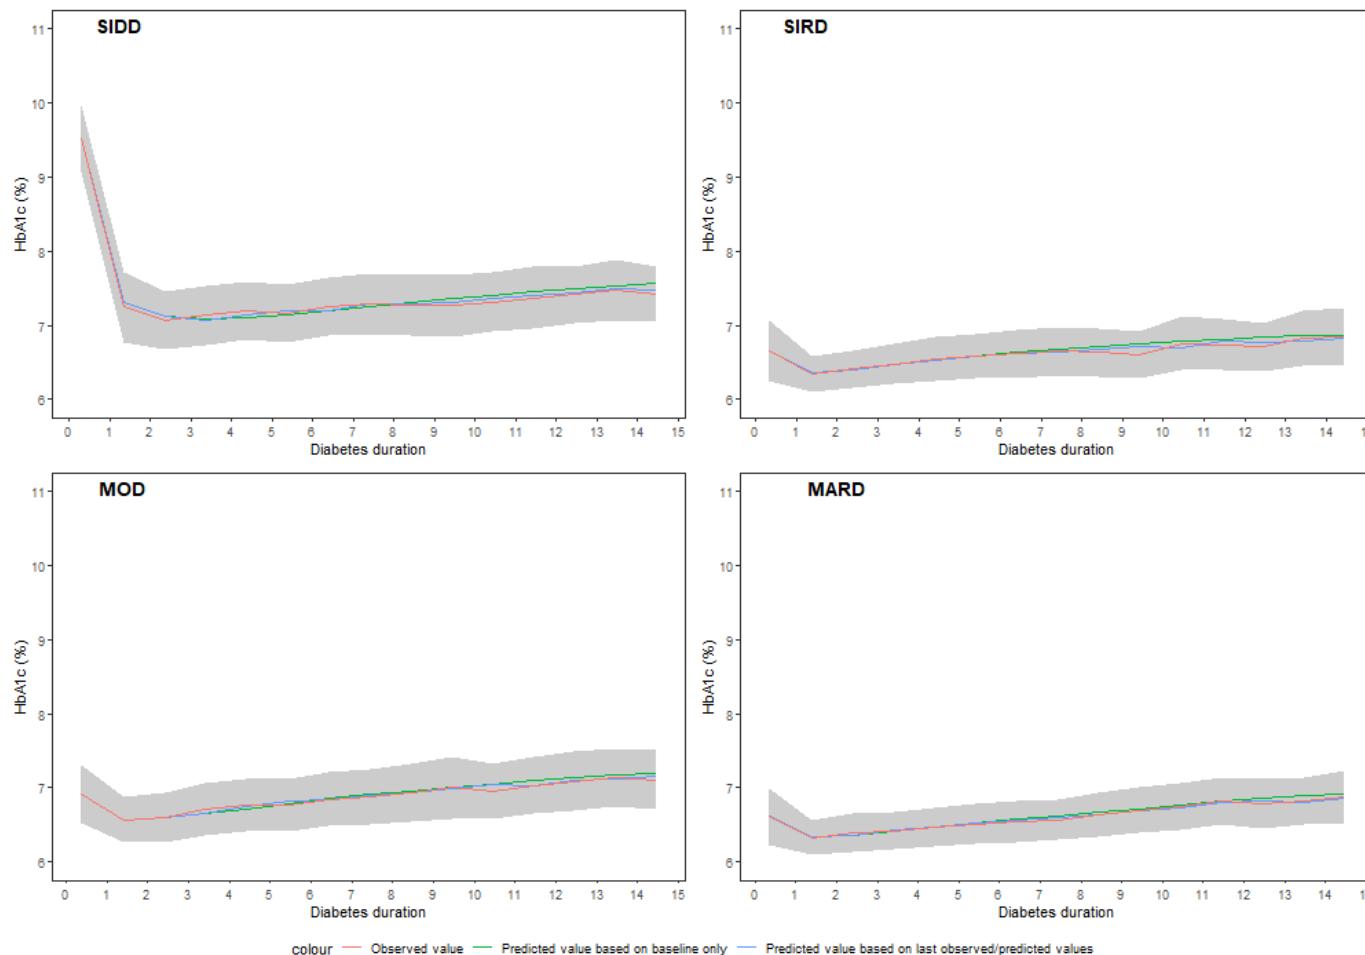

Figure 10.2 Violin graphs and pairwise comparisons of baseline clustering indicators of Ahlqvist's data-driven subgroups

The Games-Howell test was applied to enable pairwise comparison and p values were adjusted by using Benjamini-Hochberg correction to account for false discovery rate. P-values below 0.05 were considered statistically significant.

These are the baseline characteristics at diagnosis, rather than the baseline simulation characteristics.

Figure 10.3 The graphs for goodness-of-fit over time for HbA1c of each Ahlqvist's data-driven subgroup

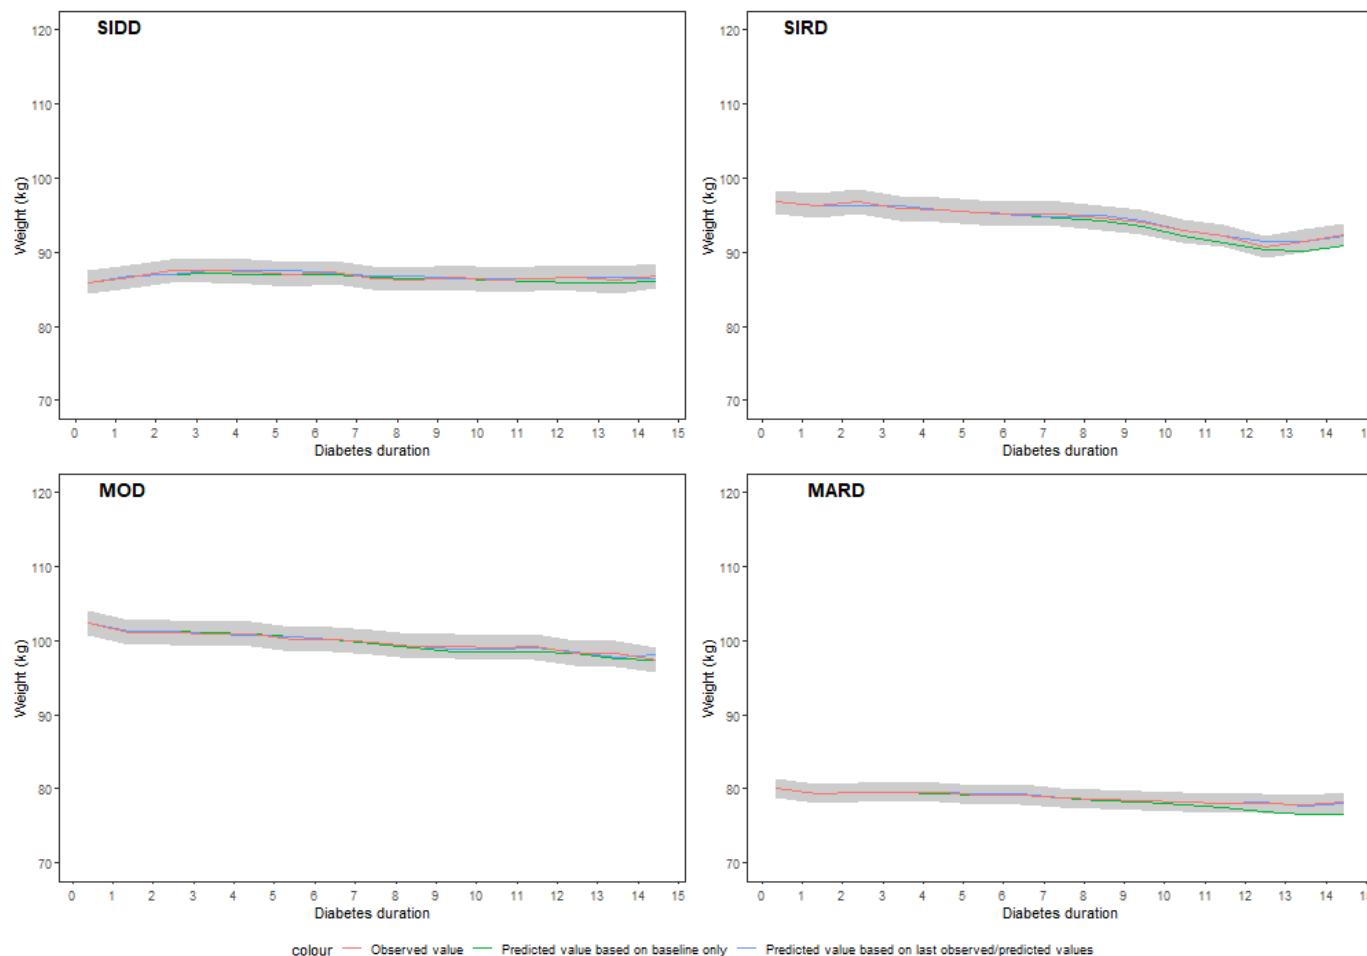

Grey area indicated 95% confidence interval of observed data.

Observed value (red line) denotes the observational data.

Predicted value based on baseline only (green line) denotes the values extrapolated based on only baseline value.

Predicted value based on last observed/predicted (blue line) denotes the values extrapolated based on baseline value and available data observed during follow-up.

Figure 10.4 The graphs for goodness-of-fit over time for weight of each Ahlqvist's data-driven subgroup

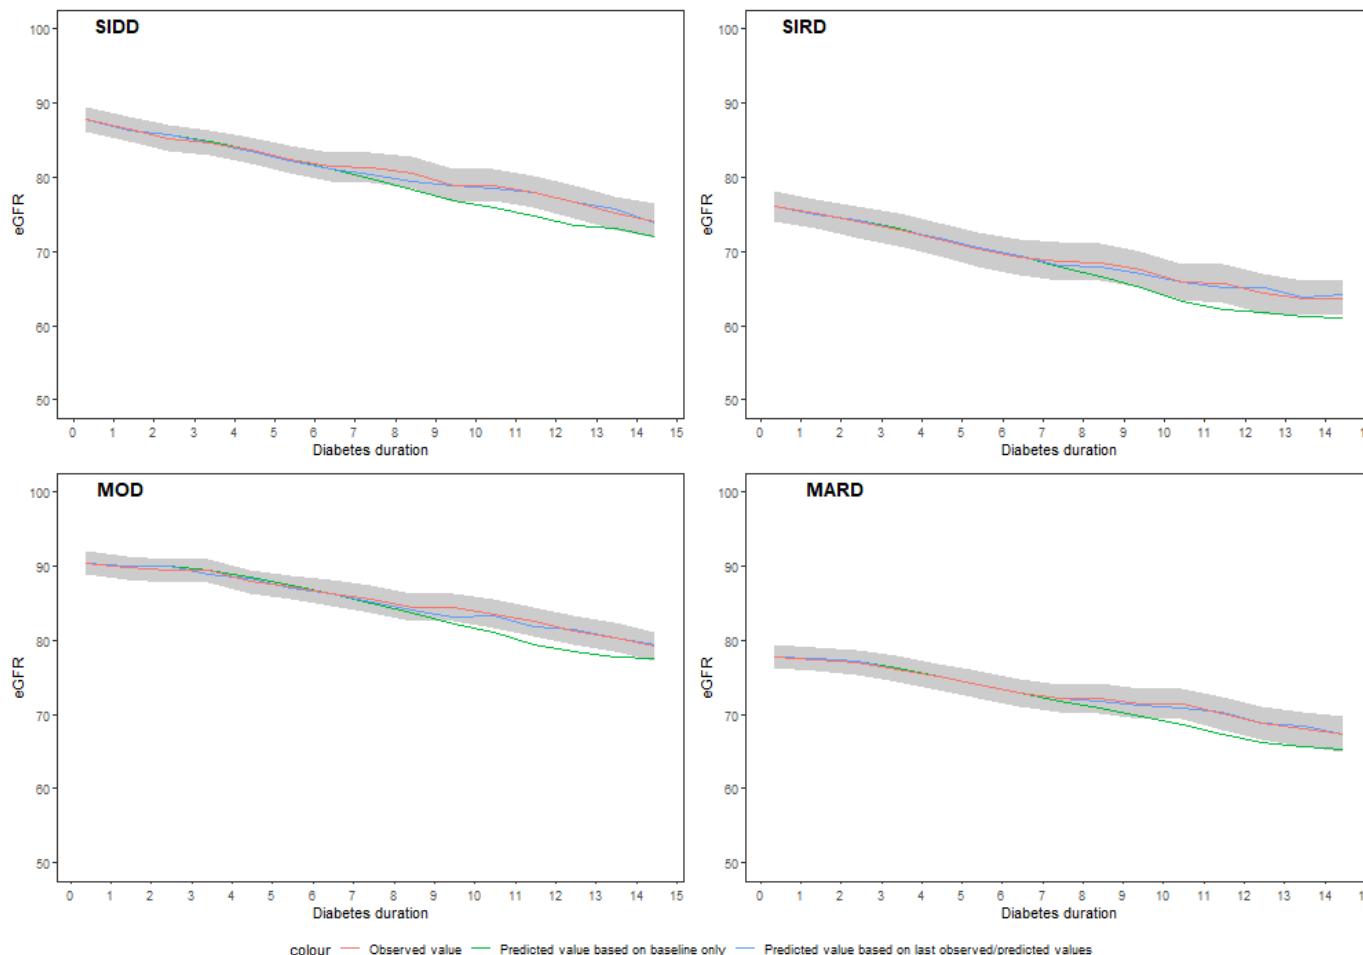

Grey area indicated 95% confidence interval of observed data.

Observed value (red line) denotes the observational data.

Predicted value based on baseline only (green line) denotes the values extrapolated based on only baseline value.

Predicted value based on last observed/predicted (blue line) denotes the values extrapolated based on baseline value and available data observed during follow-up.

Figure 10.5 The graphs for goodness-of-fit over time for eGFR of each Ahlqvist's data-driven subgroup

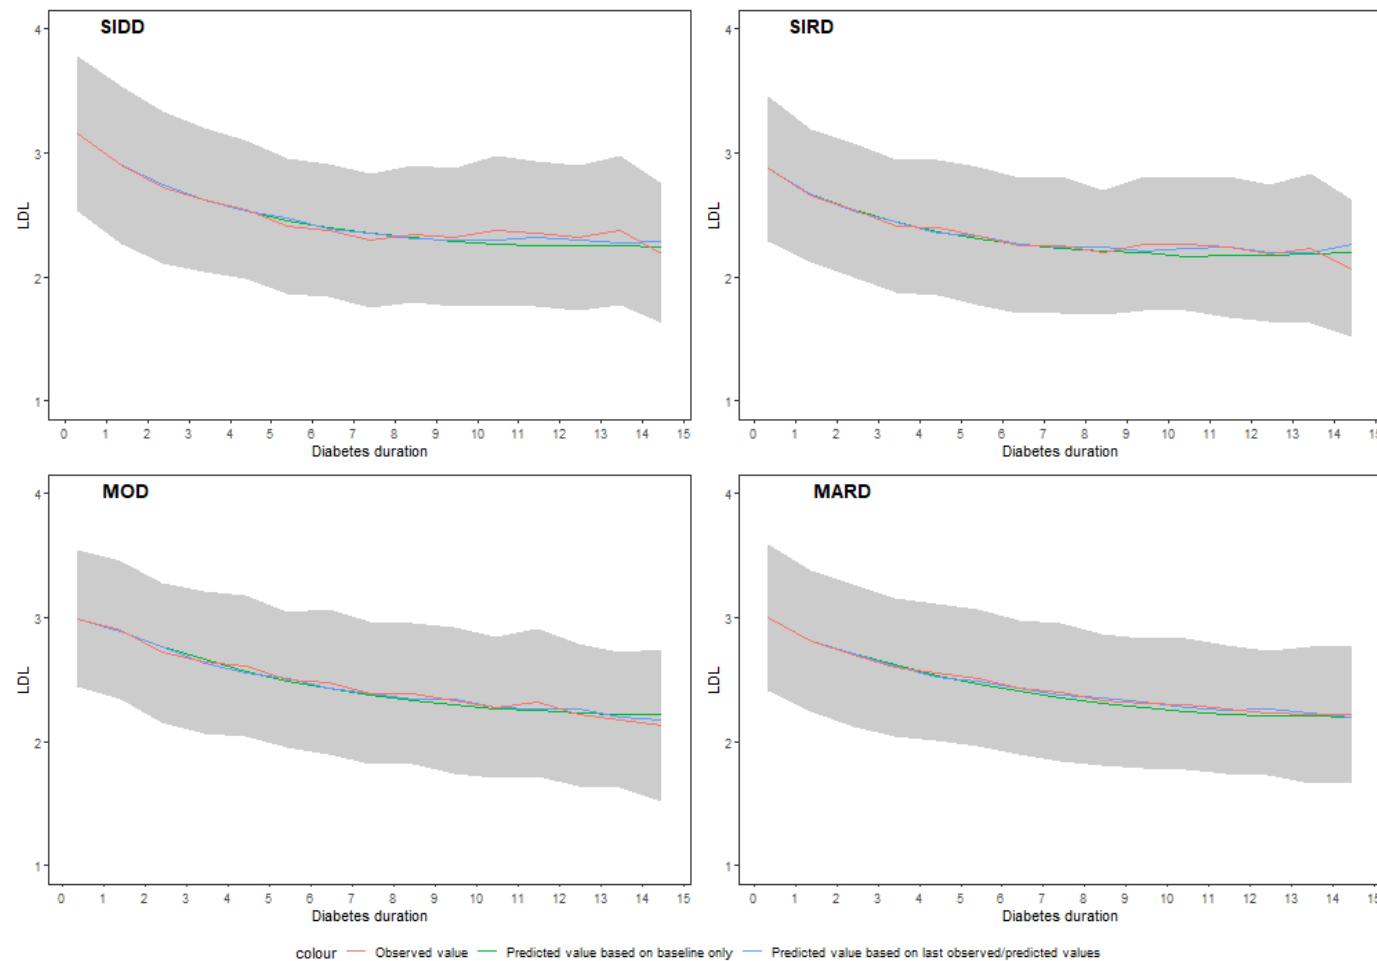

Grey area indicated 95% confidence interval of observed data.

Observed value (red line) denotes the observational data.

Predicted value based on baseline only (green line) denotes the values extrapolated based on only baseline value.

Predicted value based on last observed/predicted (blue line) denotes the values extrapolated based on baseline value and available data observed during follow-up.

Figure 10.6 The graphs for goodness-of-fit over time for LDL of each Ahlqvist's data-driven subgroup

Grey area indicated 95% confidence interval of observed data.

Observed value (red line) denotes the observational data.

Predicted value based on baseline only (green line) denotes the values extrapolated based on only baseline value.

Predicted value based on last observed/predicted (blue line) denotes the values extrapolated based on baseline value and available data observed during follow-up.

Figure 10.7 Non-standardized and standardized mean simulated lifetime QALYs and cost with 95% CI (in U.S. setting) for Ahlqvist's data-driven clustering subgroups

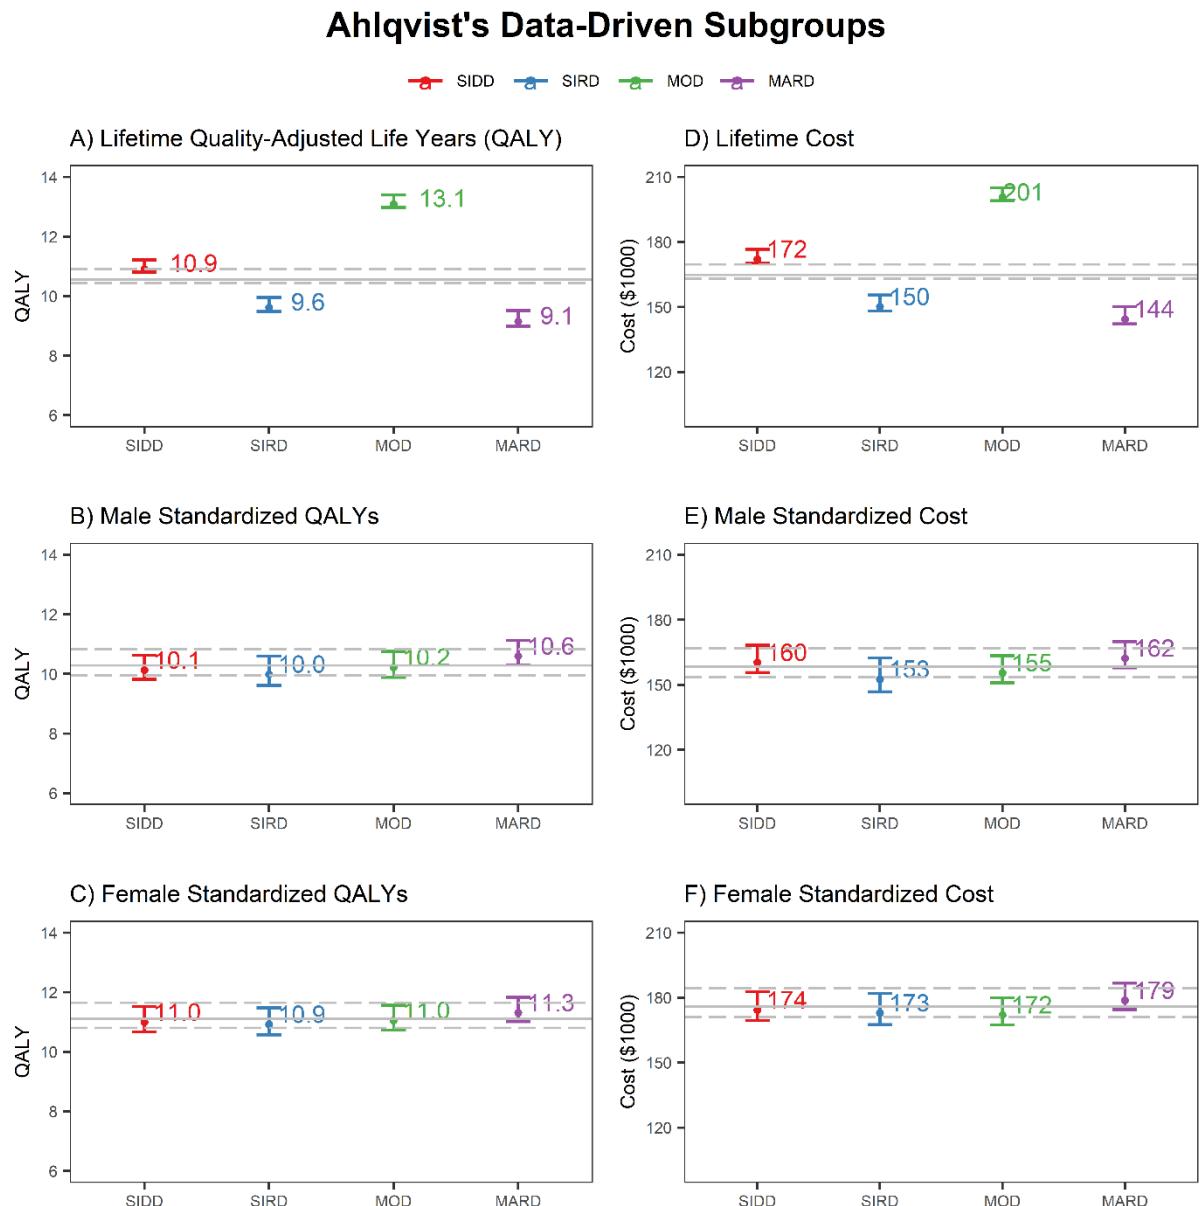

Figure 10.8 Non-standardized and standardized mean simulated lifetime QALYs and cost with 95% CI (in U.K. setting) for Ahlqvist's data-driven clustering subgroups

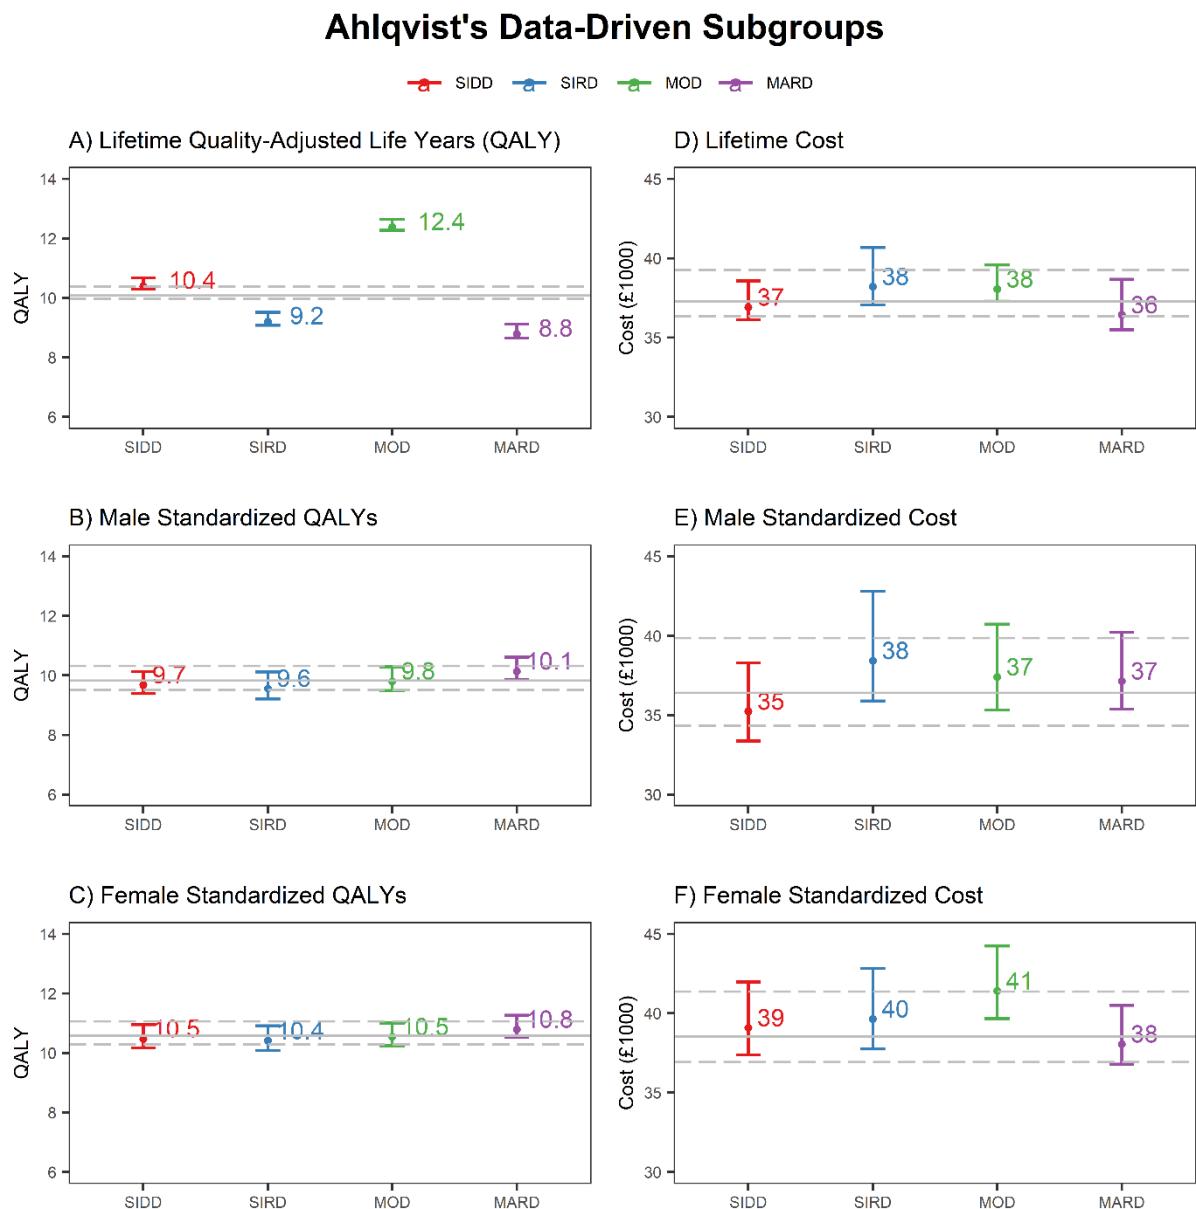

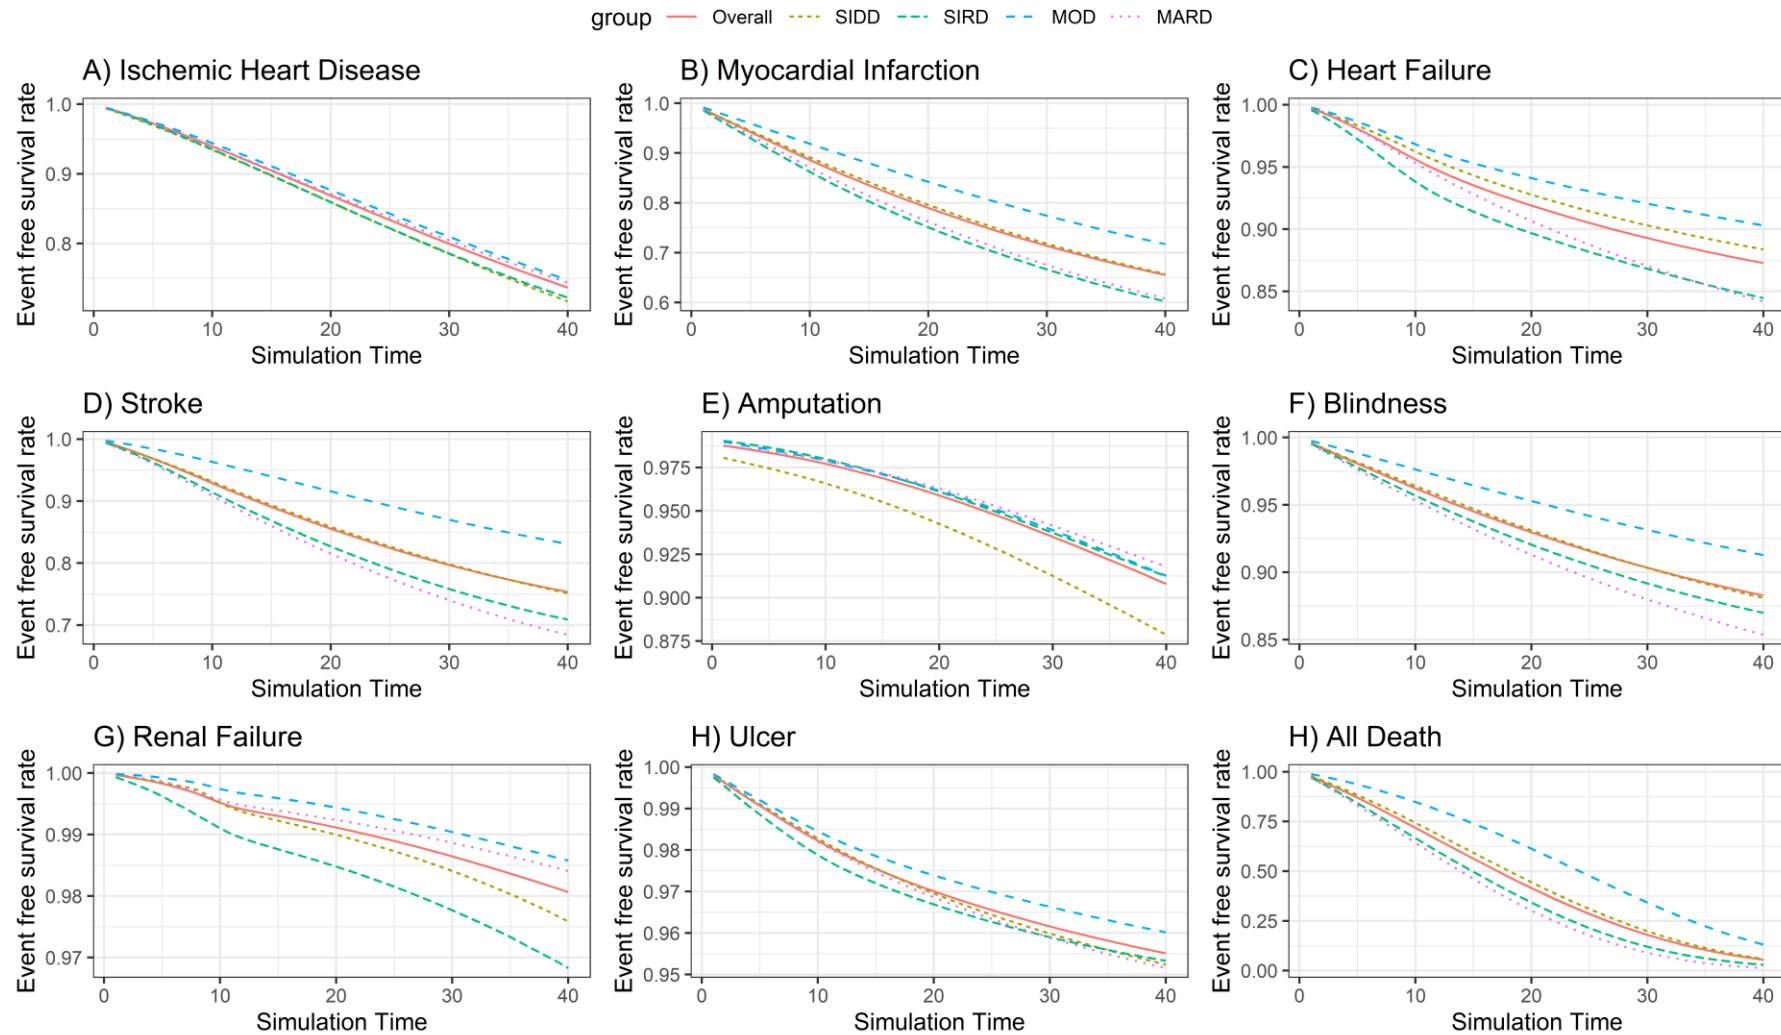

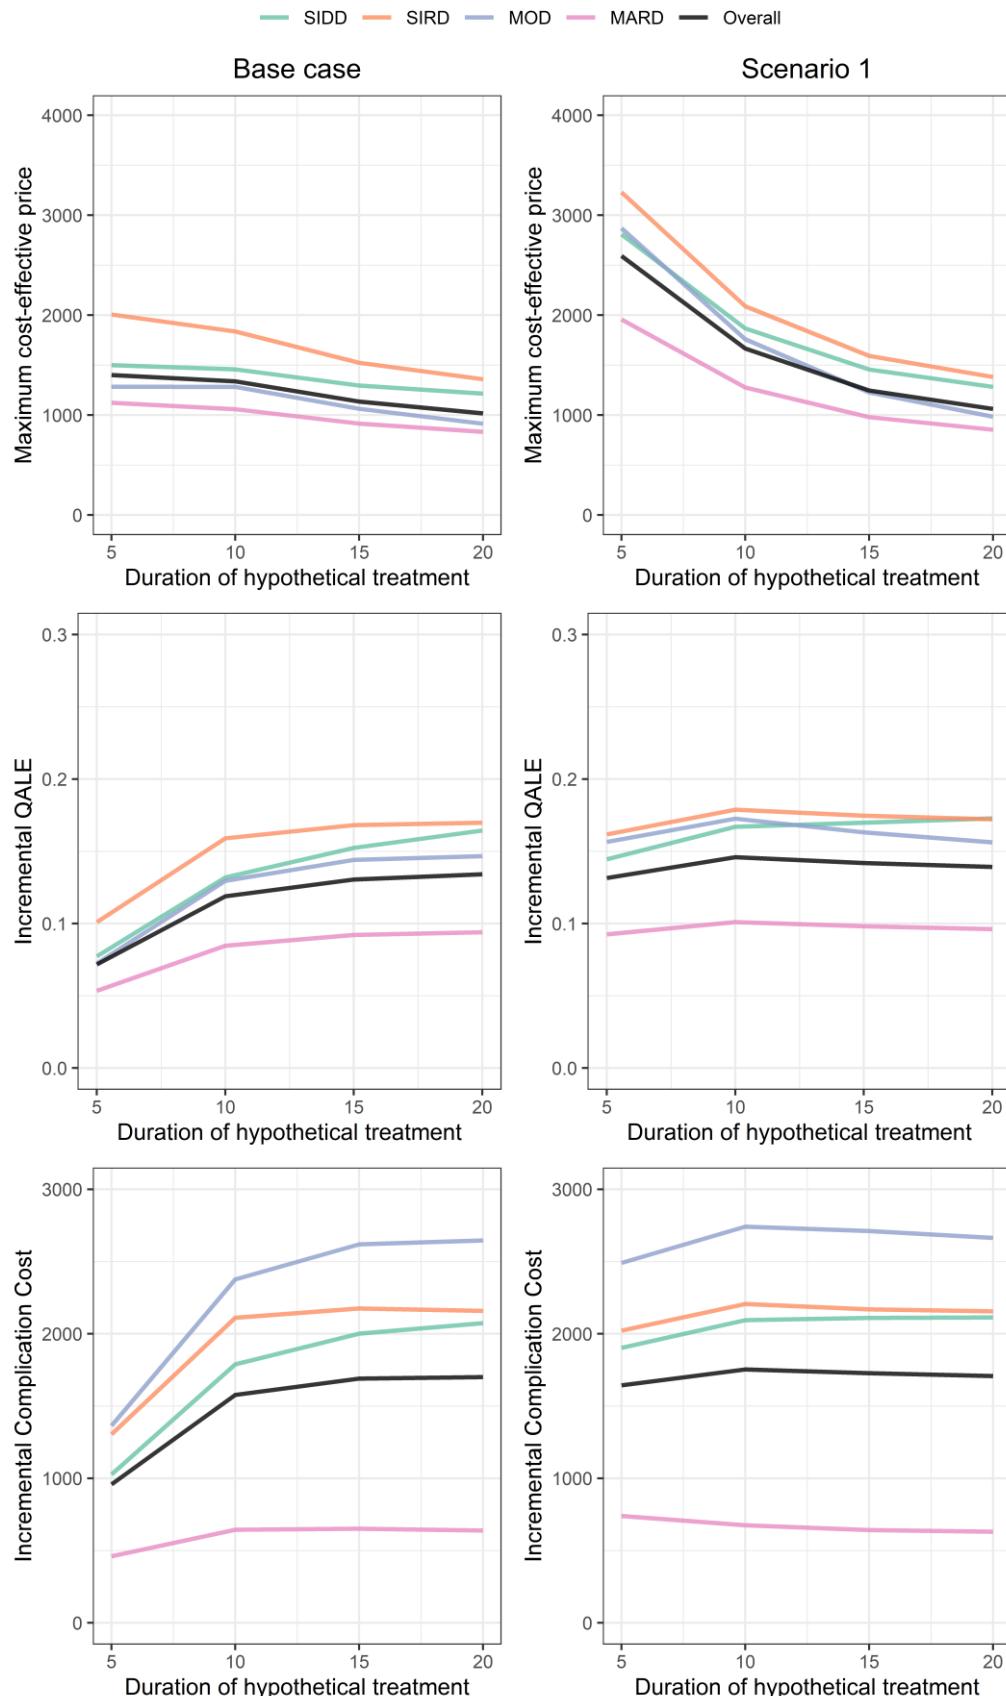

Figure 10.9 Simulated Kaplan-Meier plots of Ahlqvist's data-driven subgroups

Kaplan-Meier survival plots by year of simulation for each event are generated simulated by the model for each subgroup. Higher value indicates less risky.  
Blindness refers to blindness in one eye.

Figure 10.10 Maximum annual cost-effective price, incremental QALYs and complication costs of multiple-year guideline-based intensive management targeting HbA1c, BMI and LDL by Ahlqvist's data-driven subgroups (in U.S. setting), for a range of treatment durations
